Preface

This document describes KiCS2 (Kiel Curry System Version 2), an implementation of the multi-paradigm language Curry [15, 26] that is based on compiling Curry programs into Haskell programs. Curry is a universal programming language aiming at the amalgamation of the most important declarative programming paradigms, namely functional programming and logic programming. Curry combines in a seamless way features from functional programming (nested expressions, lazy evaluation, higher-order functions), logic programming (logical variables, partial data structures, built-in search), and concurrent programming (concurrent evaluation of constraints with synchronization on logical variables). The current KiCS2 implementation does not support concurrent constraints. Alternatively, one can write distributed applications by the use of sockets that can be registered and accessed with symbolic names. Moreover, KiCS2 also supports the high-level implementation of graphical user interfaces and web services (as described in more detail in [16, 17, 18, 21]).

We assume familiarity with the ideas and features of Curry as described in the Curry language definition [26]. Therefore, this document only explains the use of the different components of KiCS2 and the differences and restrictions of KiCS2 (see Section 1.3) compared with the language Curry (Version 0.9.0). The basic ideas of the implementation of KiCS2 can be found in [11, 12].

Acknowledgements

This work has been supported in part by the DFG grants Ha 2457/5-1 and Ha 2457/5-2.
1 Overview of KiCS2

1.1 Installation

This version of KiCS2 has been developed and tested on Linux systems. In principle, it should be also executable on other platforms on which a Haskell implementation (Glasgow Haskell Compiler and Cabal) exists, like in many Linux distributions, Sun Solaris, or Mac OS X systems.

Installation instructions for KiCS2 can be found in the file INSTALL.txt stored in the KiCS2 installation directory. Note that KiCS2 can be installed with experimental support for profiling of executables. To use profiling, two requirements have to be met:

- The libraries that are shipped with the GHC that is used by KiCS2 have to be installed with profiling enabled. This is the default for the system libraries contained in the GHC release, but may not be the case for additional libraries.

- The Makefile of KiCS2 contains an option PROFILING which has to be set to yes to enable profiling support. You may either change the Makefile to

  PROFILING = yes

  or specify this setting while starting the installation process using

  make <optional target> PROFILING=yes

In the following, kics2home denotes the installation directory of the KiCS2 installation.

1.2 General Use

All executables required to use the different components of KiCS2 are stored in the directory kics2home/bin. You should add this directory to your path (e.g., by the bash command “export PATH=kics2home/bin:$PATH”).

The source code of the Curry program must be stored in a file with the suffix “.curry”, e.g., prog.curry. Literate programs must be stored in files with the extension “.lcurry”.

Since the translation of Curry programs with KiCS2 creates some auxiliary files (see Section D for details), you need write permission in the directory where you have stored your Curry programs. The auxiliary files for all Curry programs in the current directory can be deleted by the command cleancurry

(this is a shell script stored in the bin directory of the KiCS2 installation, see above). The command cleancurry -r also deletes the auxiliary files in all subdirectories.

1.3 Restrictions

There are a few minor restrictions on Curry programs when they are processed with KiCS2:

- Singleton pattern variables, i.e., variables that occur only once in a rule, should be denoted as an anonymous variable “_”, otherwise the parser will print a warning since this is a typical source of programming errors.
KiCS2 translates all local declarations into global functions with additional arguments ("lambda lifting", see Appendix D of the Curry language report). Thus, in the various run-time systems, the definition of functions with local declarations look different from their original definition (in order to see the result of this transformation, you can use the CurryBrowser, see Section 8).

Tabulator stops instead of blank spaces in source files are interpreted as stops at columns 9, 17, 25, 33, and so on. In general, tabulator stops should be avoided in source programs.

Encapsulated search: The general definition of encapsulated search of the Curry report [25] is not supported. Thus, the corresponding prelude operations like try, solveAll, once, findAll, or best are not defined in the KiCS2 prelude. However, KiCS2 supports appropriate alternatives to encapsulate non-deterministic computations:

**Strong encapsulation:** This means that all potential non-determinism is encapsulated. Since this might result in dependencies on the evaluation strategy (see [9] for a detailed discussion), this kind of encapsulation is only available as I/O operations. For instance, the library AllSolutions (Section A.2.1) defines the operation
getAllValues :: a → IO [a]

to compute all values of a given argument expression. There is also the library SearchTree (Section A.3.7) which supports user-programmable search strategies and contains some predefined strategies like depth-first, breadth-first, iterative deepening search.

**Weak encapsulation:** This means that only the non-determinism defined inside an encapsulation operator is encapsulated. Conceptually, these operators are offered as set functions [3] which compute the set of all results but do not encapsulate non-determinism in the actual arguments. See the library SetFunctions (Section A.2.34) for more details.

Concurrent computations based on the suspension of expressions containing free variables are not yet supported. KiCS2 supports value generators for free variables so that a free variable is instantiated when its value is demanded. For instance, the initial expression

x == True where x free

is non-deterministically evaluated to False and True by instantiating x to False and True, respectively. Thus, a computation is never suspended due to free variables. This behavior also applies to free variables of primitive types like integers. For instance, the initial expression

x*y:=:=1 where x,y free

is non-deterministically evaluated to the two solutions

{x = -1, y = -1} True
{x = 1, y = 1} True

Unification is performed without an occur check.

There is currently no general connection to external constraint solvers.
1.4 Modules in KiCS2

KiCS2 searches for imported modules in various directories. By default, imported modules are searched in the directory of the main program and the system module directory “kics2home/lib”. This search path can be extended by setting the environment variable CURRYPATH (which can be also set in a KiCS2 session by the option “:set path”, see below) to a list of directory names separated by colons (“:”). In addition, a local standard search path can be defined in the “.kics2rc” file (see Section 2.7). Thus, modules to be loaded are searched in the following directories (in this order, i.e., the first occurrence of a module file in this search path is imported):

1. Current working directory (“.”) or directory prefix of the main module (e.g., directory “/home/joe/curryprogs” if one loads the Curry program “/home/joe/curryprogs/main”).

2. The directories enumerated in the environment variable CURRYPATH.

3. The directories enumerated in the “.kics2rc” variable “libraries”.

4. The directory “kics2home/lib”.

The same strategy also applies to modules with a hierarchical module name with the only difference that the hierarchy prefix of a module name corresponds to a directory prefix of the module. For instance, if the main module is stored in directory MAINDIR and imports the module Test.Func, then the module stored in MAINDIR/Test/Func.curry is imported (without setting any additional import path) according to the module search strategy described above.

Note that the standard prelude (“kics2home/lib/Prelude.curry”) will be always implicitly imported to all modules if a module does not contain an explicit import declaration for the module Prelude.
2 Using the Interactive Environment of KiCS2

This section describes the interactive environment KiCS2 that supports the development of applications written in Curry. The implementation of KiCS2 contains also a separate compiler which is automatically invoked by the interactive environment.

2.1 Invoking KiCS2

To start KiCS2, execute the command “kics2” or “curry” (these are shell scripts stored in kics2home/bin where kics2home is the installation directory of KiCS2). When the system is ready (i.e., when the prompt “Prelude>” occurs), the prelude (kics2home/lib/Prelude.curry) is already loaded, i.e., all definitions in the prelude are accessible. Now you can type various commands (see next section) or an expression to be evaluated.

One can also invoke KiCS2 with parameters. These parameters are usual a sequence of commands (see next section) that are executed before the user interaction starts. For instance, the invocation

```
kics2 :load Mod :add List
```

starts KiCS2, loads the main module Mod, and adds the additional module List. The invocation

```
kics2 :load Mod :eval config
```

starts KiCS2, loads the main module Mod, and evaluates the operation config before the user interaction starts. As a final example, the invocation

```
kics2 :load Mod :save :quit
```

starts KiCS2, loads the main module Mod, creates an executable, and terminates KiCS2. This invocation could be useful in “make” files for systems implemented in Curry.

There are also some specific options that can be used when invoking KiCS2:

- `-h` or `--help`: Print only a help message.

- `-V` or `--version`: Print the version information of KiCS2 and quit.

- `--compiler-name`: Print just the compiler name (kics2) and quit.

- `--numeric-version`: Print just the version number and quit.

- `--noredline` (if used, this must be the first option): Do not use input line editing (see Section 2.6).

- `--name=val` (these options must come before any KiCS2 command): Overwrite values defined in the configuration file “.kics2rc” (see Section 2.7), where name is a property defined in the configuration file and val its new value.

One can also invoke KiCS2 with some run-time arguments that can be accessed inside a Curry program by the I/O operation `getArgs` (see library System (Section A.2.37). These run-time arguments must be written at the end after the separator “--”. For instance, if KiCS2 is invoked by

```
kics2 :load Mod -- first and second
```
then a call to the I/O operation `getArgs` returns the list value

`["first","and","second"]`

### 2.2 Commands of KiCS2

The most important commands of KiCS2 are (it is sufficient to type a unique prefix of a command if it is unique, e.g., one can type “:r” instead of “:reload”):

- **:help**  Show a list of all available commands.
- **:load prog**  Compile and load the program stored in `prog.curry` together with all its imported modules.
- **:reload**  Recompile all currently loaded modules.
- **:compile prog**  Compile and load the program stored in `prog.curry`, as with the command “:load prog”, but compile also the generated Haskell modules. Usually, this is automatically done when an expression is evaluated. Hence, it is not necessary to use this command.
- **:add m₁...mₙ**  Add modules `m₁,...,mₙ` to the set of currently loaded modules so that their exported entities are available in the top-level environment.
- **:expr expr**  Evaluate the expression `expr` to normal form and show the computed results. In the default mode, all results of non-deterministic computations are printed. One can also print first one result and the next result only if the user requests it. This behavior can be set by the option `interactive` (see below).

**Free variables in initial expressions** must be declared as in Curry programs. In order to see the results of their bindings, they must be introduced by a “where...free” declaration. For instance, one can write

```
not b where b free
```

in order to obtain the following bindings and results:

```
{b = False} True
{b = True} False
```

Without these declarations, an error is reported in order to avoid the unintended introduction of free variables in initial expressions by typos.

If the free variables in the initial goal are of a polymorphic type, as in the expression

```
xs++ys=:=[z] where xs,ys,z free
```

they are specialized to the type “Ω” (since the current implementation of KiCS2 does not support computations with polymorphic logic variables).

---

1Currently, bindings are only printed if the initial expression is not an I/O action (i.e., not of type “IO...”) and there are not more than ten free variables in the initial expression.
:eval expr  Same as expr. This command might be useful when putting commands as arguments when invoking kics2.

:quit  Exit the system.

There are also a number of further commands that are often useful:

:type expr  Show the type of the expression expr.

:programs  Show the list of all Curry programs that are available in the load path.

:cd dir  Change the current working directory to dir.

:edit  Load the source code of the current main module into a text editor. If the variable editcommand is set in the configuration file “.kics2rc” (see Section 2.7), its value is used as an editor command, otherwise the environment variable “EDITOR” is used as the editor program.

:edit m  Load the source text of module m (which must be accessible via the current load path if no path specification is given) into a text editor which is defined as in the command “:edit”.

:show  Show the source text of the currently loaded Curry program. If the variable showcommand is set in the configuration file “.kics2rc” (see Section 2.7), its value is used as a command to show the source text, otherwise the environment variable PAGER (or “cat”, if PAGER is undefined) is used to show the source text.

:show m  Show the source text of module m which must be accessible via the current load path if no path specification is given.

:source f  Show the source code of function f (which must be visible in the currently loaded module) in a separate window.

:source m.f  Show the source code of function f defined in module m in a separate window.

:browse  Start the CurryBrowser to analyze the currently loaded module together with all its imported modules (see Section 8 for more details).

:interface  Show the interface of the currently loaded module, i.e., show the names of all imported modules, the fixity declarations of all exported operators, the exported datatypes declarations and the types of all exported functions.

:interface m  Similar to “:interface” but shows the interface of the module m which must be in the load path of KiCS2.

:usedimports  Show all calls to imported functions in the currently loaded module. This might be useful to see which import declarations are really necessary.

:set option  Set or turn on/off a specific option of the KiCS2 environment (see 2.3 for a description of all options). Options are turned on by the prefix “+” and off by the prefix “-”. Options that can only be set (e.g., path) must not contain a prefix.
:set Show a help text on the possible options together with the current values of all options.

:save Save the currently loaded program as an executable evaluating the main expression “main”. The executable is stored in the file Mod if Mod is the name of the currently loaded main module.

:save expr Similar as “:save” but the expression expr (typically: a call to the main function) will be evaluated by the executable.

:fork expr The expression expr, which is typically of type “IO ()”, is evaluated in an independent process which runs in parallel to the current KiCS2 process. All output and error messages from this new process are suppressed. This command is useful to test distributed Curry programs where one can start a new server process by this command. The new process will be terminated when the evaluation of the expression expr is finished.

:!cmd Shell escape: execute cmd in a Unix shell.

2.3 Options of KiCS2

The following options (which can be set by the command “:set”) are currently supported:

path path Set the additional search path for loading modules to path. Note that this search path is only used for loading modules inside this invocation of KiCS2.

The path is a list of directories separated by “:”. The prefix “~” is replaced by the home directory as in the following example:

:set path aux:~/tests

Relative directory names are replaced by absolute ones so that the path is independent of later changes of the current working directory.

bfs Set the search mode to evaluate non-deterministic expressions to breadth-first search. This is the default search strategy. Usually, all non-deterministic values are enumerated and printed with a breadth-first strategy, but one can also print only the first value or all values by interactively requesting them (see below for these options).

dfs Similarly to bfs but use a depth-first search strategy to compute and print the values of the initial expression.

ids Similarly to bfs but use an iterative-deepening strategy to compute and print the values of the initial expression. The initial depth bound is 100 and the depth-bound is doubled after each iteration.

ids n Similarly to ids but use an initial depth bound of n.

parallel Similarly to bfs but use a parallel search strategy to compute and print the values of the initial expression. The system chooses an appropriate number of threads according the current number of available processors.

parallel n Similarly to parallel but use n parallel threads.
**prdfs** Set the search mode to evaluate non-deterministic expressions to primitive depth-first search. This is usually the fastest method to print all non-deterministic values. However, it does not support the evaluation of values by interactively requesting them.

**choices n** Show the internal choice structure (according to the implementation described in [11]) resulting from the complete evaluation of the main expression in a tree-like structure. This mode is only useful for debugging or understanding the implementation of non-deterministic evaluations used in KiCS2. If the optional argument \( n \) is provided, the tree is shown up to depth \( n \).

**supply i** (only available in the local compilation mode, see below) Use implementation \( i \) as the identifier supply for choice structures (see [11] for a detailed explanation). Currently, the following values for \( i \) are supported:

- **integer**: Use unbounded integers as choice identifiers. This implementation is described in [11].
- **ghc** (default): Use a more sophisticated implementation of choice identifiers (based on the ideas described in [8]) provided by the Glasgow Haskell Compiler.
- **pureio**: Use IO references (i.e., memory cells) for choice identifiers. This is the most efficient implementation for top-level depth-first search but cannot be used for more sophisticated search methods like encapsulated search.
- **ioref**: Use a mixture of ghc and pureio. IO references are used for top-level depth-first search and ghc identifiers are used for encapsulated search methods.

**v** Set the verbosity level to \( n \). The following values are allowed for \( n \):

- \( n = 0 \): Do not show any messages (except for errors).
- \( n = 1 \): Show only messages of the front-end, like loading of modules.
- \( n = 2 \): Show also messages of the back end, like compilation messages from the Haskell compiler.
- \( n = 3 \): Show also intermediate messages and commands of the compilation process.
- \( n = 4 \): Show also all intermediate results of the compilation process.

**prompt p** Sets the user prompt which is shown when KiCS2 is waiting for input. If the parameter \( p \) starts with a letter or a percent sign, the prompt is printed as the given parameter, where the sequence “%s” is expanded to the list of currently loaded modules and “%%” is expanded to a percent sign. If the prompt starts with a double quote, it is read as a string and, therefore, also supports the normal escape sequences that can occur in Curry programs. The default setting is

: set prompt "%s> "

**+/-interactive** Turn on/off the interactive mode. In the interactive mode, the next non-deterministic value is only computed when the user requests it. Thus, one has also the possibility to terminate the enumeration of all values after having seen some values.
Turn on/off the first-only mode. In the first-only mode, only the first value of the main expression is printed (instead of all values).

Turn on/off the optimization of the target program.

Turn on/off the binding mode. If the binding mode is on (default), then the bindings of the free variables of the initial expression are printed together with the result of the expression.

Turn on/off the time mode. If the time mode is on, the cpu time and the elapsed time of the computation is always printed together with the result of an evaluation.

Turn on/off the trace mode. If the trace mode is on, it is possible to trace the sources of failing computations.

(only available when configured during installation, see Section 1.1) Turn on/off the profile mode. If the profile mode is on, expressions as well as programs are compiled with GHC’s profiling capabilities enabled. For expressions, evaluation will automatically generate a file `Main.prof` containing the profiling information of the evaluation. For compiled programs, the profiling has to be manually activated using runtime options when executed:

```
kics2 :set +profile :load MyProgram.curry :save :quit
./MyProgram +RTS -p -RTS [additional arguments]
```

Turn on/off the local compilation and linking mode. In the standard execution mode of KiCS2, the local mode is turned off so that compiled Curry programs are linked against pre-compiled libraries that are packaged with Cabal. This makes the compilation and linking process faster so that this is the preferred execution mode. However, one cannot change the system libraries and directly use these changed libraries. Therefore, for experimental purposes, one can use the local mode. In this mode, a compiled Curry program is linked against the current versions of the system libraries which might require their re-compilation. Hence, it is important for the local mode that KiCS2 is installed in a local directory where one has write access, otherwise this mode might not work.

Note that some options for experimenting with KiCS2 (like `supply` or `ghc`) are available only in the local compilation mode (since they require the recompilation of parts of the installed system).

Turn on/off the ghci mode. In the ghci mode, the initial goal is send to the interactive version of the Glasgow Haskell Compiler. This might result in a slower execution but in a faster startup time since the linker to create the main executable is not used.

Turn on/off the safe execution mode. In the safe execution mode, the initial goal is not allowed to be of type `IO` and the program should not import the module `Unsafe`. Furthermore, the allowed commands are `eval`, `load`, `quit`, and `reload`. This mode is useful to use KiCS2 in uncontrolled environments, like a computation service in a web page, where KiCS2 could be invoked by

```
kics2 :set safe
```
**parser opts** Define additional options passed to the KiCS2 front end, i.e., the parser program

```
:kics2home/bin/kics2-frontend
```

For instance, setting the option

```
:set parser -F --pgmF=transcurry
```

has the effect that each Curry module to be compiled is transformed by the preprocessor command `transcurry` into a new Curry program which is actually compiled.

**cmp opts** Define additional options passed to the KiCS2 compiler. For instance, setting the option

```
:set cmp -O 0
```

has the effect that all optimizations performed by the KiCS2 compiler are turned off.

**ghc opts** Define additional options passed to the Glasgow Haskell Compiler (GHC) when the generated Haskell programs are compiled. Many options necessary to compile Curry programs are already set (you can see them by setting the verbosity level to 2 or greater). One has to be careful when providing additional options. For instance, in the default global installation of KiCS2, libraries are pre-compiled so that inconsistencies might occur if compilation options might be changed.

It is safe to pass specific GHC linking options. For instance, to enforce the static linking of libraries in order to generate an executable (see command “:save”) that can be executed in another environment, one could set the options

```
:set ghc -static -optl-static -optl-pthread
```

Other options are useful for experimental purposes, but those should be used only in the local compilation mode (see above) to avoid inconsistent target codes for different libraries. For instance, setting the option

```
:set ghc -DDISABLE_CS
```

has the effect that the constraint store used to enable an efficient access to complex bindings is disabled. Similarly,

```
:set ghc -DSTRICT_VAL_BIND
```

has the effect that expressions in a unification constraint (=:=) are always fully evaluated (instead of the evaluation to a head normal form only) before unifying both sides. Since these options influence the compilation of the run-time system, one should also enforce the recompilation of Haskell programs by the GHC option “-fforce-recomp”, e.g., one should set

```
:set ghc -DDISABLE_CS -fforce-recomp
```

**rts opts** Define additional run-time options passed to the executable generated by the Glasgow Haskell Compiler, i.e., the parameters “*RTS o -RTS” are passed to the executable. For instance, setting the option

```
:set rts -H512m
```

has the effect that the minimum heap size is set to 512 megabytes.
Define run-time arguments passed to the executable generated by the Glasgow Haskell Compiler. For instance, setting the option

   :set args first second

has the effect that the I/O operation getArgs (see library System (Section A.2.37) returns the value "first","second".

2.4 Source-File Options

If the evaluation of operations in some main module loaded into KiCS2 requires specific options, like an iterative-deepening search strategy, one can also put these options into the source code of this module in order to avoid setting these options every time when this module is loaded. Such source-file options must occur before the module header, i.e., before the first declaration (module header, imports, fixity declaration, defining rules, etc) occurring in the module. Each source file option must be in a line of the form

   {-# KiCS2_OPTION opt #-}

where opt is an option that can occur in a ":set" command (compare Section 2.3). Such a line in the source code (which is a comment according to the syntax of Curry) has the effect that this option is set by the KiCS2 command ":set opt" whenever this module is loaded (not reloaded!) as a main module. For instance, if a module starts with the lines

   {-# KiCS2_OPTION ids #-}
   {-# KiCS2_OPTION +ghci #-}
   {-# KiCS2_OPTION v2 #-}
   module M where
   ...

then the load command ":load M" will also set the options for iterative deepening, using ghci and verbosity level 2.

2.5 Using KiCS2 in Batch Mode

Although KiCS2 is primarily designed as an interactive system, it can also be used to process data in batch mode. For example, consider a Curry program, say myprocessor, that reads argument strings from the command line and processes them. Suppose the entry point is a function called just_doit that takes no arguments. Such a processor can be invoked from the shell as follows:

   > kics2 :set args string1 string2 :load myprocessor.curry :eval just_doit :quit

The ":quit" directive is necessary to avoid KiCS2 going into interactive mode after the execution of the expression being evaluated. The actual run-time arguments (string1, string2) are defined by setting the option args (see above).

   Here is an example to use KiCS2 in this way:

   > kics2 :set args Hello World :add System :eval "getArgs >>= putStrLn . unwords" :quit
   Hello World
   >
2.6 Command Line Editing

In order to have support for line editing or history functionality in the command line of KiCS2 (as often supported by the `readline` library), you should have the Unix command `rlwrap` installed on your local machine. If `rlwrap` is installed, it is used by KiCS2 if called on a terminal. If it should not be used (e.g., because it is executed in an editor with `readline` functionality), one can call KiCS2 with the parameter “--noredline” (which must occur as the first parameter).

2.7 Customization

In order to customize the behavior of KiCS2 to your own preferences, there is a configuration file which is read by KiCS2 when it is invoked. When you start KiCS2 for the first time, a standard version of this configuration file is copied with the name “.kics2rc” into your home directory. The file contains definitions of various settings, e.g., about showing warnings, using Curry extensions, programs etc. After you have started KiCS2 for the first time, look into this file and adapt it to your own preferences.

2.8 Emacs Interface

Emacs is a powerful programmable editor suitable for program development. It is freely available for many platforms (see http://www.emacs.org). The distribution of KiCS2 contains also a special Curry mode that supports the development of Curry programs in the Emacs environment. This mode includes support for syntax highlighting, finding declarations in the current buffer, and loading Curry programs into KiCS2 in an Emacs shell.

The Curry mode has been adapted from a similar mode for Haskell programs. Its installation is described in the file README in directory “kics2home/tools/emacs” which also contains the sources of the Curry mode and a short description about the use of this mode.
3 Extensions

KiCS2 supports some extensions in Curry programs that are not (yet) part of the definition of Curry. These extensions are described below.

3.1 Narrowing on Int Literals

In addition to narrowing on algebraic data types, KiCS2 also implements narrowing on values of the primitive type \texttt{Int}. For example, the goal “\texttt{x == 3 where x free}” is evaluated to the solutions

\begin{verbatim}
Prelude> x == 3 where x free
{x = (-x2) } False
{x = 0 } False
{x = 1 } False
{x = (2 * _x3) } False
{x = 3 } True
{x = (4 * _x4 + 1)} False
{x = (4 * _x4 + 3)} False
\end{verbatim}

Note that the free variables occurring in the binding are restricted to positive numbers greater than 0 (the output has been indented to increase readability). This feature is implemented by an internal binary representation of integer numbers. If necessary, this representation can be exposed to the user by setting the flag \texttt{BinaryInt} during installation:

\texttt{make [kernel|install] RUNTIMEFLAGS=BinaryInt}

In an experimental (local) installation, the flag can also be set in the interpreter:

\begin{verbatim}
:set ghc -DBinaryInt
\end{verbatim}

The example above will then be evaluated (without indentation) to:

\begin{verbatim}
Prelude> x == 3 where x free
{x = (Neg _x2) } False
{x = 0 } False
{x = 1 } False
{x = (Pos (O _x3)) } False
{x = 3 } True
{x = (Pos (I (O _x4)))} False
{x = (Pos (I (I _x4))))} False
\end{verbatim}

In this output, values without free variables are presented as before. For values containing a free variable, the constructors \texttt{Neg} and \texttt{Pos} denote negative and positive numbers (without 0), while the constructors \texttt{O} and \texttt{I} denote a 0– and 1–bit where the \textit{least significant bit comes first}. That is, \texttt{(Pos (I (0 _x4)))} = \texttt{+(I (0 _x4))} = \texttt{+(2 * (0 _x4))} + 1 = \texttt{+(4 * _x4) + 1} which meets the output above.

3.2 Recursive Variable Bindings

Local variable declarations (introduced by \texttt{let} or \texttt{where}) can be (mutually) recursive in KiCS2. For instance, the declaration
introduces the local variable `ones` which is bound to a cyclic structure representing an infinite list of 1’s. Similarly, the definition

```haskell
onetwo n = take n one2
  where
    one2 = 1 : two1
    two1 = 2 : one2
```

introduces a local variable `one2` that represents an infinite list of alternating 1’s and 2’s so that the expression `(onetwo 6)` evaluates to `[1,2,1,2,1,2]`.

### 3.3 Functional Patterns

Functional patterns [2] are a useful extension to implement operations in a more readable way. Furthermore, defining operations with functional patterns avoids problems caused by strict equality ("=:=") and leads to programs that are potentially more efficient.

Consider the definition of an operation to compute the last element of a list `xs` based on the prelude operation "++" for list concatenation:

```haskell
last xs | _++[y] =:= xs = y where y free
```

Since the equality constraint "=:=" evaluates both sides to a constructor term, all elements of the list `xs` are fully evaluated in order to satisfy the constraint.

Functional patterns can help to improve this computational behavior. A functional pattern is a function call at a pattern position. With functional patterns, we can define the operation `last` as follows:

```haskell
last (_++[y]) = y
```

This definition is not only more compact but also avoids the complete evaluation of the list elements: since a functional pattern is considered as an abbreviation for the set of constructor terms obtained by all evaluations of the functional pattern to normal form (see [2] for an exact definition), the previous definition is conceptually equivalent to the set of rules

- `last [y] = y`
- `last [_,y] = y`
- `last [_,_,y] = y`

... which shows that the evaluation of the list elements is not demanded by the functional pattern.

In general, a pattern of the form `(f t₁...tₙ)` for `n > 0` (or of the qualified form `(M.f t₁...tₙ)` for `n ≥ 0`) is interpreted as a functional pattern if `f` is not a visible constructor but a defined function that is visible in the scope of the pattern. Furthermore, for a functional pattern to be well defined, there are two additional requirements to be satisfied:

1. If a function `f` is defined by means of a functional pattern `fp`, then the evaluation of `fp` must not depend on `f`, i.e., the semantics of a function defined using functional patterns must not (transitively) depend on its own definition. This excludes definitions such as
\[(xs ++ ys) ++ zs = xs ++ (ys ++ zs)\]

and is necessary to assign a semantics to functions employing functional patterns (see [2] for more details).

2. Only functions that are globally defined may occur inside a functional pattern. This restriction ensures that no local variable might occur in the value of a functional pattern, which might lead to an non-intuitive semantics. Consider, for instance, the following (complicated) equality operation

\[
eq :: a \to a \to \text{Bool} \\
eq x y = h y \\
\text{where} \\
g \text{True} = x \\
h (g a) = a
\]

where the locally defined function \(g\) occurs in the functional pattern \((g a)\) of \(h\). Since \((g a)\) evaluates to the value of \(x\) whereas \(a\) is instantiated to \(\text{True}\), the call \(h y\) now evaluates to \(\text{True}\) if the value of \(y\) equals the value of \(x\). In order to check this equality condition, a strict unification between \(x\) and \(y\) is required so that an equivalent definition without functional patterns would be:

\[
eq :: a \to a \to \text{Bool} \\
eq x y = h y \\
\text{where} \\
h x_1 \mid x =:= x_1 = \text{True}
\]

However, this implies that variables occurring in the value of a functional pattern imply a strict unification if they are defined in an outer scope, whereas variables defined inside a functional pattern behave like pattern variables. In consequence, the occurrence of variables from an outer scope inside a functional pattern might lead to an non-intuitive behavior. To avoid such problems, locally defined functions are excluded as functional patterns. Note that this does not exclude a functional pattern inside a local function, which is still perfectly reasonable.

It is also possible to combine functional patterns with as-patterns. Similarly to the meaning of as-patterns in standard constructor patterns, as-patterns in functional patterns are interpreted as a sequence of pattern matching where the variable of the as-pattern is matched before the given pattern is matched. This process can be described by introducing an auxiliary operation for this two-level pattern matching process. For instance, the definition

\[
f (_ ++ x0[(42,\_)] ++ _) = x
\]

is considered as syntactic sugar for the expanded definition

\[
f (_ ++ x ++ _) = f' x \\
\text{where} \\
f' [(42,\_)] = x
\]

However, as-patterns are usually implemented in a more efficient way without introducing auxiliary operations.
### 3.4 Order of Pattern Matching

Curry allows multiple occurrences of pattern variables in standard patterns. These are an abbreviation of equational constraints between pattern variables. Functional patterns might also contain multiple occurrences of pattern variables. For instance, the operation

\[
f (\_++[x]++\_++[x]++\_) = x
\]

returns all elements with at least two occurrences in a list.

If functional patterns as well as multiple occurrences of pattern variables occur in a pattern defining an operation, there are various orders to match an expression against such an operation. In the current implementation, the order is as follows:

1. Standard pattern matching: First, it is checked whether the constructor patterns match. Thus, functional patterns and multiple occurrences of pattern variables are ignored.

2. Functional pattern matching: In the next phase, functional patterns are matched but occurrences of standard pattern variables in the functional patterns are ignored.

3. Non-linear patterns: If standard and functional pattern matching is successful, the equational constraints which correspond to multiple occurrences pattern variables are solved.

4. Guards: Finally, the guards supplied by the programmer are checked.

The order of pattern matching should not influence the computed result. However, it might have some influence on the termination behavior of programs, i.e., a program might not terminate instead of finitely failing. In such cases, it could be necessary to consider the influence of the order of pattern matching. Note that other orders of pattern matching can be obtained using auxiliary operations.
4 Recognized Syntax of Curry

The KiCS2 Curry compiler accepts a slightly extended version of the grammar specified in the Curry Report [26]. Furthermore, the syntax recognized by KiCS2 differs from that specified in the Curry Report regarding numeric or character literals. We therefore present the complete description of the syntax below, whereas syntactic extensions are highlighted.

4.1 Notational Conventions

The syntax is given in extended Backus-Naur-Form (eBNF), using the following notation:

- \textit{NonTerm} ::= \textit{α} production
- \textit{NonTerm} nonterminal symbol
- \textit{Term} terminal symbol
- \textit{[α]} optional
- \textit{\{α\}} zero or more repetitions
- \textit{(α)} grouping
- \textit{α | β} alternative
- \textit{α ⟨β⟩} difference – elements generated by \textit{α} without those generated by \textit{β}

The Curry files are expected to be encoded in UTF8. However, source programs are biased towards ASCII for compatibility reasons.

4.2 Lexicon

4.2.1 Comments

Comments either begin with “--” and terminate at the end of the line, or begin with “{-” and terminate with a matching “-}”, i.e., the delimiters “{-” and “-}” act as parentheses and can be nested.

4.2.2 Identifiers and Keywords

The case of identifiers is important, i.e., the identifier “abc” is different from “ABC”. Although the Curry Report specifies four different case modes (Prolog, Gödel, Haskell, free), the KiCS2 only supports the \textit{free} mode which puts no constraints on the case of identifiers in certain language constructs.

- \textit{Letter} ::= any ASCII letter
- \textit{Dashes} ::= -- \{-\}
- \textit{Ident} ::= (Letter \{Letter | Digit | _ | \'}\})\}_{ReservedID}
- \textit{Symbol} ::= ~ | ! | @ | # | $ | % | ^ | & | * | + | - | = | < | > | ? | . | / | | | \ :
- \textit{ModuleID} ::= \{Ident .\} Ident
- \textit{TypeConstrID} ::= Ident
- \textit{TypeVarID} ::= Ident | _
- \textit{DataConstrID} ::= Ident
InfixOpID ::= (Symbol {Symbol}) ⟨Dashes | ReservedSym⟩
FunctionID ::= Ident
VariableID ::= Ident
LabelID ::= Ident
QTypeConstrID ::= [ModuleID .] TypeConstrID
QDataConstrID ::= [ModuleID .] DataConstrID
QInfixOpID ::= [ModuleID .] InfixOpID
QFunctionID ::= [ModuleID .] FunctionID
QLabelID ::= [ModuleID .] LabelID

The following identifiers are recognized as keywords and cannot be used as regular identifiers.
ReservedID ::= case | data | do | else | external | fcase | foreign
| free | if | import | in | infix | infixl | infixr
| let | module | newtype | of | then | type | where

Note that the identifiers as, hiding and qualified are no keywords. They have only a special
meaning in module headers and can thus be used as ordinary identifiers elsewhere. The following
symbols also have a special meaning and cannot be used as an infix operator identifier.
ReservedSym ::= . . | : | : . | = | \ | | | <- | -> | @ | ~

4.2.3 Numeric and Character Literals

In contrast to the Curry Report, KiCS2 adopts Haskell’s notation of literals for both numeric as
well as character and string literals, extended with the ability to denote binary integer literals.

Int ::= Decimal
| 0b Binary | 0B Binary
| 0o Octal | 0O Octal
| 0x Hexadecimal | 0X Hexadecimal

Float ::= Decimal . Decimal [Exponent]
| Decimal Exponent
Exponent ::= (e | E) [+ | -] Decimal

Decimal ::= Digit {Digit}
Binary ::= Binit {Binit}
Octal ::= Octit {Octit}
Hexadecimal ::= Hexit {Hexit}

Digit ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
Binit ::= 0 | 1
Octit ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7
Hexit ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | A | B | C | D | E | F | a | b | c | d | e | f

For character and string literals, the syntax is as follows:
Char ::= ' (Graphic | Space | Escape ) '
String ::= " {Graphic | \ | Space | Escape | Gap } "
Escape ::= \ (CharEsc | AsciiEsc | Decimal | o Octal | x Hexadecimal)
CharEsc ::= a | b | f | n | r | t | v | \ | " | ' | &
AsciiEsc ::= ^ Cntrl | NUL | SOH | STX | ETX | EOT | ENQ | ACK

23
4.3 Layout

Similarly to Haskell, a Curry programmer can use layout information to define the structure of blocks. For this purpose, we define the indentation of a symbol as the column number indicating the start of this symbol, and the indentation of a line is the indentation of its first symbol.2

The layout (or “off-side”) rule applies to lists of syntactic entities after the keywords let, where, do, or of. In the subsequent context-free syntax, these lists are enclosed with curly braces ({ }) and the single entities are separated by semicolons (;). Instead of using the curly braces and semicolons of the context-free syntax, a Curry programmer can also specify these lists by indentation: the indentation of a list of syntactic entities after let, where, do, or of is the indentation of the next symbol following the let, where, do, or of. Any item of this list starts with the same indentation as the list. Lines with only whitespaces or an indentation greater than the indentation of the list continue the item in the previous line. Lines with an indentation less than the indentation of the list terminate the entire list. Moreover, a list started by let is terminated by the keyword in. Thus, the sentence

\[ f \ x = h \ x \ \text{where} \ \{ \ g \ y = y + 1 ; \ h \ z = (g \ z) \times 2 \} \]

which is valid w.r.t. the context-free syntax, can be written with the layout rules as

\[ f \ x = h \ x \]
\[ \text{where} \ g \ y = y + 1 \]
\[ h \ z = (g \ z) \times 2 \]

or also as

\[ f \ x = h \ x \ \text{where} \]
\[ g \ y = y + 1 \]
\[ h \ z = (g \ z) \times 2 \]

To avoid an indentation of top-level declarations, the keyword module and the end-of-file token are assumed to start in column 0.

4.4 Context-Free Grammar

\[
\text{Module} ::= \text{module ModuleID [Exports] where Block}
\]
\[
\text{Block} ::= \{ \text{[ImportDecls] ;| BlockDecl}_1 ; \ldots ; \text{BlockDecl}_n \} \ (\text{no fixity declarations here, } n \geq 0)
\]

---

2In order to determine the exact column number, we assume a fixed-width font with tab stops at each 8th column.
Exports ::= ( Export_1, ..., Export_n )  
  (n ≥ 0)

Export ::= QFunction  
| QTypeConstr [ ( ConsLabel_1, ..., ConsLabel_n ) ]  
  (n ≥ 0)
| QTypeConstr (...)  
| module ModuleID

ConsLabel ::= DataConstr | Label

ImportDecls ::= ImportDecl_1 ; ... ; ImportDecl_n  
  (n ≥ 1)

ImportDecl ::= import [qualified] ModuleID [as ModuleID] | ImportSpec  
| hiding ( Import_1, ..., Import_n )  
  (n ≥ 0)

Import ::= Function  
| QTypeConstr [ ( ConsLabel_1, ..., ConsLabel_n ) ]  
  (n ≥ 0)
| QTypeConstr ( ... )

BlockDecl ::= TypeSynDecl  
| DataDecl  
| NewtypeDecl  
| FixityDecl  
| FunctionDecl

TypeSynDecl ::= type SimpleType = TypeExpr  
  (n ≥ 0)

SimpleType ::= TypeConstrID TypeVarID_1 ... TypeVarID_n  
  (n ≥ 0)

DataDecl ::= data SimpleType  
| data SimpleType = ConstrDecl_1 | ... | ConstrDecl_n  
  (n ≥ 1)

ConstrDecl ::= DataConstr SimpleTypeExpr_1 ... SimpleTypeExpr_n  
  (n ≥ 0)
| TypeConsExpr ConOp TypeConsExpr  
  (infix data constructor)
| DataConstr { FieldDecl_1, ..., FieldDecl_n }  
  (n ≥ 0)

FieldDecl ::= Label_1, ..., Label_n :: TypeExpr  
  (n ≥ 1)

NewtypeDecl ::= newtype SimpleType = NewConstrDecl

NewConstrDecl ::= DataConstr SimpleTypeExpr  
| DataConstr { Label :: TypeExpr }  
| TypeConsExpr -> TypeExpr

TypeConsExpr ::= QTypeConstrID SimpleTypeExpr_1 ... SimpleTypeExpr_n  
  (n ≥ 1)
| SimpleTypeExpr

SimpleTypeExpr ::= TypeVarID  
| QTypeConstrID  
| ()  
  (unit type)
| ( TypeExpr_1, ..., TypeExpr_n )  
  (tuple type, n ≥ 2)
| [ TypeExpr ]  
  (list type)
| ( TypeExpr )  
  (parenthesized type)

FixityDecl ::= Fixity [Int] Op_1, ..., Op_n  
  (n ≥ 1)

Fixity ::= infixl | infiir | infix

FunctionDecl ::= Signature | ExternalDecl | Equation

Signature ::= Functions :: TypeExpr

ExternalDecl ::= Functions external  
  (externally defined functions)

Functions ::= Function_1, ..., Function_n  
  (n ≥ 1)

Equation ::= FunLhs Rhs

FunLhs ::= Function SimplePat_1 ... SimplePat_n  
  (n ≥ 0)
\[
\text{ConsPattern} \text{ FunOp ConsPattern}
(\text{FunLhs}) \text{ SimplePat}_1 \ldots \text{ SimplePat}_n, \quad (n \geq 1)
\]
\[
\text{Rhs} ::= = \text{Expr} \left[ \text{where LocalDecls} \right]
\]
\[
\text{CondExprs} ::= | \text{InfixExpr} = \text{Expr} \left[ \text{CondExprs} \right]
\]
\[
\text{LocalDecls} ::= \{ \text{LocalDecl}_1 ; \ldots ; \text{LocalDecl}_n \} \quad (n \geq 0)
\]
\[
\text{LocalDecl} ::= \text{FunctionDecl} \quad | \text{PatternDecl} \quad | \text{Variable}
\]
\[
\text{SimplePat} ::= \text{Variable} \quad | \_ \quad | \text{GDataConstr} \quad | \text{Literal} \quad | (\text{Pattern}) \quad | (\text{Pattern}_1, \ldots, \text{Pattern}_n) \quad | [\text{Pattern}_1, \ldots, \text{Pattern}_n] \quad | \text{Variable} \oplus \text{SimplePat} \quad | \text{SimplePat} \quad | \text{QFunction}\text{SimplePat}_1 \ldots \text{SimplePat}_n \quad | \text{QDataConstr}\{\text{FieldPat}_1, \ldots, \text{FieldPat}_n\}
\]
\[
\text{FieldPat} ::= \text{QLabel} = \text{Pattern}
\]
\[
\text{Expr} ::= \text{InfixExpr} :: : \text{TypeExpr}
\]
\[
\text{InfixExpr} ::= \text{NoOpExpr} \text{QOp InfixExpr} \quad (\text{infix operator application})
\]
\[
\text{NoOpExpr} ::= \backslash \text{SimplePat}_1 \ldots \text{SimplePat}_n \rightarrow \text{Expr} \quad (\text{lambda expression}, n \geq 1)
\]
\[
\text{FuncExpr} ::= [\text{FuncExpr}] \text{BasicExpr} \quad (\text{application})
\]
\[
\text{BasicExpr} ::= \text{Variable} \quad (\text{variable})
\]
\[
\text{FieldPat} ::= \text{QLabel} = \text{Pattern}
\]

GConSym ::= : | QInfixOpID
5 Optimization of Curry Programs

After the invocation of the Curry front end, which parses a Curry program and translates it into the intermediate FlatCurry representation, KiCS2 applies a transformation to optimize Boolean equalities occurring in the Curry program. The ideas and details of this optimization are described in [5]. Therefore, we sketch only some basic ideas and options to influence this optimization.

Consider the following definition of the operation last to extract the last element in list:

\[
\text{last } xs \mid xs == _++[x] = x
\]

where \(x\) free

In order to evaluate the condition “\(xs == _++[x]\)”, the Boolean equality is evaluated to True or False by instantiating the free variables _ and x. However, since we know that a condition must be evaluated to True only and all evaluations to False can be ignored, we can use the constrained equality to obtain a more efficient program:

\[
\text{last } xs \mid xs =:= _++[x] = x
\]

where \(x\) free

Since the selection of the appropriate equality operator is not obvious and might be tedious, KiCS2 encourages programmers to use only the Boolean equality operator “==” in programs. The constraint equality operator “=:=" can be considered as an optimization of “==” if it is ensured that only positive results are required, e.g., in conditions of program rules.

To support this programming style, KiCS2 has a built-in optimization phase on FlatCurry files. For this purpose, the optimizer analyzes the FlatCurry programs for occurrences of “==” and replaces them by “=:=" whenever the result False is not required. The usage of the optimizer can be influenced by setting the property flag bindingoptimization in the configuration file .kics2rc. The following values are recognized for this flag:

no: Do not apply this transformation.

fast: This is the default value. The transformation is based on pre-computed values for the prelude operations in order to decide whether the value False is not required as a result of a Boolean equality. Hence, the transformation can be efficiently performed without any complex analysis.

full: Perform a complete “required values” analysis of the program (see [5]) and use this information to optimize programs. In most cases, this does not yield better results so that the fast mode is sufficient.

Hence, to turn off this optimization, one can either modify the flag bindingoptimization in the configuration file .kics2rc or dynamically pass this change to the invocation of KiCS2 by

\[ ... -Dbindingoptimization=no ... \]
6  cypm: The Curry Package Manager

The Curry package manager (CPM) is a tool to distribute and install Curry libraries and applications and manage version dependencies between these libraries. Since CPM offers a lot of functionality, there is a separate manual available.\(^3\) Therefore, we describe here only some basic CPM commands.

The executable cypm is located in the bin directory of KiCS2. Hence, if you have this directory in your path, you can start CPM by cloning a copy of the central package index repository:

\[\texttt{cypm update}\]

Now you can show a short list of all packages in this index by

\[\texttt{cypm list}\]

<table>
<thead>
<tr>
<th>Name</th>
<th>Synopsis</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>------</td>
<td>----------</td>
<td>----------</td>
</tr>
<tr>
<td>addtypes</td>
<td>A tool to add missing type signatures in a Curry program</td>
<td>0.0.1</td>
</tr>
<tr>
<td>binint</td>
<td>Libraries with a binary representation of natural and integers</td>
<td>0.0.1</td>
</tr>
</tbody>
</table>

The command

\[\texttt{cypm info PACKAGE}\]

can be used to show more information about the package with name PACKAGE.

Some packages do not contain only useful libraries but also tools with some binary. In order to install such tools, one can use the command

\[\texttt{cypm install PACKAGE}\]

This command checks out the package in some internal directory ($HOME/.cpm/app_packages) and installs the binary of the tool provided by the package in $HOME/.cpm/bin. Hence it is recommended to add this directory to your path.

For instance, the most recent version of CPM can be installed by the following commands:

\[\texttt{cypm update}\]
\[\texttt{cypm install cpm}\]

Package 'cpm-xxx' checked out ...

INFO  Installing executable 'cypm' into '/home/joe/.cpm/bin'

Now, the binary cypm of the most recent CPM version can be used if $HOME/.cpm/bin is in your path (before $kiics2home/bin!).

A detailed description how to write your own packages with the use of other packages can be found in the manual of CPM.

\(^3\)http://curry-language.org/tools/cpm
CurryCheck is a tool that supports the automation of testing Curry programs. The tests to be executed can be unit tests as well as property tests parameterized over some arguments. The tests can be part of any Curry source program and, thus, they are also useful to document the code. CurryCheck is based on EasyCheck [13]. Actually, the properties to be tested are written by combinators proposed for EasyCheck, which are actually influenced by QuickCheck [14] but extended to the demands of functional logic programming.

7.1 Testing Properties

To start with a concrete example, consider the following naive definition of reversing a list:

\[
\text{rev} :: [a] \rightarrow [a] \\
\text{rev} \; [] = [] \\
\text{rev} \; (x:xs) = \text{rev} \; xs \; ++ \; [x]
\]

To get some confidence in the code, we add some unit tests, i.e., test with concrete test data:

\[
\text{revNull1} = \text{rev} \; [] \; -=- \; [] \\
\text{rev123} = \text{rev} \; [1,2,3] \; -=- \; [3,2,1]
\]

The operator “\(-=-\)” specifies a test where both sides must have a single identical value. Since this operator (as many more, see below) are defined in the library Test.Prop, we also have to import this library. Apart from unit tests, which are often tedious to write, we can also write a property, i.e., a test parameterized over some arguments. For instance, an interesting property of reversing a list is the fact that reversing a list two times provides the input list:

\[
\text{revRevIsId} \; xs = \text{rev} \; (\text{rev} \; xs) \; -=- \; xs
\]

Note that each property is defined as a Curry operation where the arguments are the parameters of the property. Altogether, our program is as follows:

```curry
module Rev(rev) where

import Test.Prop

rev :: [a] \rightarrow [a] \\
rev \; [] = [] \\
rev \; (x:xs) = rev \; xs \; ++ \; [x]

revNull1 = rev \; [] \; -=- \; [] \\
rev123 = rev \; [1,2,3] \; -=- \; [3,2,1]

revRevIsId \; xs = rev \; (rev \; xs) \; -=- \; xs
```

---

4The library Test.Prop is a clone of the library Test.EasyCheck which defines only the interface but not the actual test implementations. Thus, the library Test.Prop has less import dependencies. When CurryCheck generates programs to execute the tests, it automatically replaces references to Test.Prop by references to Test.EasyCheck in the generated programs.
Now we can run all tests by invoking the CurryCheck tool. If our program is stored in the file *Rev.curry*, we can execute the tests as follows:

```plaintext
> curry check Rev
...
Executing all tests...
revNull (module Rev, line 7):
  Passed 1 test.
rev123 (module Rev, line 8):
  Passed 1 test.
revRevIsId_ON_BASETYPE (module Rev, line 10):
  OK, passed 100 tests.
```

Since the operation `rev` is polymorphic, the property `revRevIsId` is also polymorphic in its argument. In order to select concrete values to test this property, CurryCheck replaces such polymorphic tests by defaulting the type variable to prelude type `Ordering` (the actual default type can also be set by a command-line flag). If we want to test this property on integers numbers, we can explicitly provide a type signature, where `Prop` denotes the type of a test:

```plaintext
revRevIsId :: [Int] → Prop
revRevIsId xs = rev (rev xs) == xs
```

The command `curry check` has some options to influence the output, like “-q” for a quiet execution (only errors and failed tests are reported) or “-v” for a verbose execution where all generated test cases are shown. Moreover, the return code of `curry check` is 0 in case of successful tests, otherwise, it is 1. Hence, CurryCheck can be easily integrated in tool chains for automatic testing.

In order to support the inclusion of properties in the source code, the operations defined the properties do not have to be exported, as show in the module `Rev` above. Hence, one can add properties to any library and export only library-relevant operations. To test these properties, CurryCheck creates a copy of the library where all operations are public, i.e., CurryCheck requires write permission on the directory where the source code is stored.

The library `Test.Prop` defines many combinators to construct properties. In particular, there are a couple of combinators for dealing with non-deterministic operations (note that this list is incomplete):

- The combinator “<~>” is satisfied if the set of values of both sides are equal.
- The property `x ~> y` is satisfied if `x` evaluates to every value of `y`. Thus, the set of values of `y` must be a subset of the set of values of `x`.
- The property `x <~ y` is satisfied if `y` evaluates to every value of `x`, i.e., the set of values of `x` must be a subset of the set of values of `y`.
- The combinator “<~~>” is satisfied if the multi-set of values of both sides are equal. Hence, this operator can be used to compare the number of computed solutions of two expressions.
- The property `always x` is satisfied if all values of `x` are true.
- The property `eventually x` is satisfied if some value of `x` is true.
• The property failing \( x \) is satisfied if \( x \) has no value, i.e., its evaluation fails.

• The property \( x \neq n \) is satisfied if \( x \) has \( n \) different values.

For instance, consider the insertion of an element at an arbitrary position in a list:

\[
\text{insert} \:: \, a \rightarrow [a] \rightarrow [a] \\
\text{insert} \ x \ xs \ = \ x : \ xs \\
\text{insert} \ x \ (y:ys) \ = \ y : \text{insert} \ x \ ys
\]

The following property states that the element is inserted (at least) at the beginning or the end of the list:

\[
\text{insertAsFirstOrLast} \:: \, \text{Int} \rightarrow [\text{Int}] \rightarrow \text{Prop} \\
\text{insertAsFirstOrLast} \ x \ xs \ = \ \text{insert} \ x \ xs \Rightarrow (x:xs \ ? \ xs++[x])
\]

A well-known application of \text{insert} is to use it to define a permutation of a list:

\[
\text{perm} \:: \, [a] \rightarrow [a] \\
\text{perm} \ [\] \ = \ [] \\
\text{perm} \ (x:xs) \ = \ \text{insert} \ x \ (\text{perm} \ xs)
\]

We can check whether the length of a permuted lists is unchanged:

\[
\text{permLength} \:: \, [\text{Int}] \rightarrow \text{Prop} \\
\text{permLength} \ xs \ = \ \text{length} \ (\text{perm} \ xs) \ <~> \ \text{length} \ xs
\]

Note that the use of “\(<~>\)” is relevant since we compare non-deterministic values. Actually, the left argument evaluates to many (identical) values.

One might also want to check whether \text{perm} computes the correct number of solutions. Since we know that a list of length \( n \) has \( n! \) permutations, we write the following property:

\[
\text{permCount} \:: \, [\text{Int}] \rightarrow \text{Prop} \\
\text{permCount} \ xs \ = \ \text{perm} \ xs \ # \ \text{fac} \ (\text{length} \ xs)
\]

where \text{fac} is the factorial function. However, this test will be falsified with the argument \([1,1]\). Actually, this list has only one permuted value since the two possible permutations are identical and the combinator “\(#\)” counts the number of different values. The property would be correct if all elements in the input list \( xs \) are different. This can be expressed by a conditional property: the property \( b \Rightarrow p \) is satisfied if \( p \) is satisfied for all values where \( b \) evaluates to True. Therefore, if we define a predicate \text{allDifferent} by

\[
\text{allDifferent} \ [\] \ = \ \text{True} \\
\text{allDifferent} \ (x:xs) \ = \ x \ \text{‘notElem’} \ xs \ & \ \text{allDifferent} \ xs
\]

then we can reformulate our property as follows:

\[
\text{permCount} \ xs \ = \ \text{allDifferent} \ xs \Rightarrow \text{perm} \ xs \ # \ \text{fac} \ (\text{length} \ xs)
\]

Now consider a predicate to check whether a list is sorted:

\[
\text{sorted} \:: \, [\text{Int}] \rightarrow \text{Bool} \\
\text{sorted} \ [\] \ = \ \text{True} \\
\text{sorted} \ [\_] \ = \ \text{True} \\
\text{sorted} \ (x:y:zs) \ = \ x \leq y \ & \ \text{sorted} \ (y:zs)
\]

32
This predicate is useful to test whether there are also sorted permutations:

\[
\text{permIsEventuallySorted :: } [\text{Int}] \rightarrow \text{Prop}
\]

\[
\text{permIsEventuallySorted } xs = \text{eventually } $\text{sorted (perm } xs)$
\]

The previous operations can be exploited to provide a high-level specification of sorting a list:

\[
\text{psort :: } [\text{Int}] \rightarrow [\text{Int}]
\]

\[
\text{psort } xs \mid \text{sorted } ys = ys
\]

\[
\text{where } ys = \text{perm } xs
\]

Again, we can write some properties:

\[
\text{psortIsAlwaysSorted } xs = \text{always } $\text{sorted (psort } xs)$
\]

\[
\text{psortKeepsLength } xs = \text{length (psort } xs) \sim \text{length } xs
\]

Of course, the sort specification via permutations is not useful in practice. However, it can be used as an oracle to test more efficient sorting algorithms like quicksort:

\[
\text{qsort :: } [\text{Int}] \rightarrow [\text{Int}]
\]

\[
\text{qsort } [] = []
\]

\[
\text{qsort } (x:1) = \text{qsort (filter (<x) } l) ++ x : \text{qsort (filter (>x) } l)
\]

The following property specifies the correctness of quicksort:

\[
\text{qsortIsSorting } xs = \text{qsort } xs \sim \text{psort } xs
\]

Actually, if we test this property, we obtain a failure:

\[
> \text{curry check ExampleTests}
\]

\[
\ldots
\]

\[
\text{qsortIsSorting (module ExampleTests, line 53) failed}
\]

\[
\text{Falsified by third test.}
\]

\[
\text{Arguments:}
\]

\[
[1,1]
\]

\[
\text{Results:}
\]

\[
[1]
\]

The result shows that, for the given argument \([1,1]\), an element has been dropped in the result. Hence, we correct our implementation, e.g., by replacing \((>x)\) with \((\geq x)\), and obtain a successful test execution.

For I/O operations, it is difficult to execute them with random data. Hence, CurryCheck only supports specific I/O unit tests:

\* a ‘returns’ \(x\) is satisfied if the I/O action \(a\) returns the value \(x\).

\* a ‘sameReturns’ \(b\) is satisfied if the I/O actions \(a\) and \(b\) return identical values.

Since CurryCheck executes the tests written in a source program in their textual order, one can write several I/O tests that are executed in a well-defined order.

### 7.2 Generating Test Data

CurryCheck test properties by enumerating test data and checking a given property with these values. Since these values are generated in a systematic way, one can even prove a property if the
number of test cases is finite. For instance, consider the following property from Boolean logic:

\[
\text{neg_or } b_1 \ b_2 = \text{not } (b_1 \ || \ b_2) =\text{not } b_1 \ && \text{not } b_2
\]

This property is validated by checking it with all possible values:

```curry
> curry check -v ExampleTests
... 0: False
False
1: False
True
2: True False
3: True True

neg_or (module ExampleTests, line 67):
Passed 4 tests.
```

However, if the test data is infinite, like lists of integers, CurryCheck stops checking after a given limit for all tests. As a default, the limit is 100 tests but it can be changed by the command-line flag “-m”. For instance, to test each property with 200 tests, CurryCheck can be invoked by

```curry
> curry check -m 200 ExampleTests
```

For a given type, CurryCheck automatically enumerates all values of this type (except for function types). In KiCS2, this is done by exploiting the functional logic features of Curry, i.e., by simply collecting all values of a free variable. For instance, the library `Test.EasyCheck` defines an operation

\[
\text{valuesOf :: } a \rightarrow [a]
\]

which computes the list of all values of the given argument according to a fixed strategy (in the current implementation: randomized level diagonalization [13]). For instance, we can get 20 values for a list of integers by

```haskell
Test.EasyCheck> take 20 (valuesOf (_::[Int]))
[[], [-1], [-3], [0], [1], [-1, 0], [-2], [0, 0], [3], [-1, 1], [-3, 0], [0, 1], [2],
[-1, -1], [-5], [0, -1], [5], [-1, 2], [-9], [0, 2]]
```

Since the features of PAKCS for search space exploration are more limited, PAKCS uses in CurryCheck explicit generators for search tree structures which are defined in the module `SearchTreeGenerators`. For instance, the operations

\[
\text{genInt :: SearchTree } Int
\]

\[
\text{genList :: SearchTree } a \rightarrow \text{SearchTree } [a]
\]

generates (infinite) trees of integer and lists values. To extract all values in a search tree, the library `Test.EasyCheck` also defines an operation
valuesOfSearchTree :: SearchTree a → [a]

so that we obtain 20 values for a list of integers in PAKCS by

```haskell
...> take 20 (valuesOfSearchTree (genList genInt))
[[], [1], [1, 1], [1, -1], [2], [6], [3], [5], [0], [0, 1], [0, 0], [-1], [-1, 0], [-2],
[-3], [1, 5], [1, 0], [2, -1], [4], [3, -1]]
```

Apart from the different implementations, CurryCheck can test properties on predefined types, as already shown, as well as on user-defined types. For instance, we can define our own Peano representation of natural numbers with an addition operation and two properties as follows:

```haskell
data Nat = Z | S Nat
add :: Nat → Nat → Nat
add Z n = n
add (S m) n = S(add m n)
addIsCommutative x y = add x y == add y x
addIsAssociative x y z = add (add x y) z == add x (add y z)
```

Properties can also be defined for polymorphic types. For instance, we can define general polymorphic trees, operations to compute the leaves of a tree and mirroring a tree as follows:

```haskell
data Tree a = Leaf a | Node [Tree a]
leaves (Leaf x) = [x]
leaves (Node ts) = concatMap leaves ts
mirror (Leaf x) = Leaf x
mirror (Node ts) = Node (reverse (map mirror ts))
```

Then we can state and check two properties on mirroring:

```haskell
doubleMirror t = mirror (mirror t) == t
leavesOfMirrorAreReversed t = leaves t == reverse (leaves (mirror t))
```

In some cases, it might be desirable to define own test data since the generated structures are not appropriate for testing (e.g., balanced trees to check algorithms that require work on balanced trees). Of course, one could drop undesired values by an explicit condition. For instance, consider the following operation that adds all numbers from 0 to a given limit:

```haskell
sumUp n = if n==0 then 0 else n + sumUp (n-1)
```

Since there is also a simple formula to compute this sum, we can check it:

```haskell
sumUpIsCorrect n = n>=0 ==⇒ sumUp n == n * (n+1) \text{‘div’} 2
```

Note that the condition is important since sumUp diverges on negative numbers. CurryCheck tests this property by enumerating integers, i.e., also many negative numbers which are dropped for the tests. In order to generate only valid test data, we define our own generator for a search tree containing only valid data:

```haskell
genInt = genCons0 0 ||| genCons1 (+1) genInt
```
The combinator \texttt{genCons0} constructs a search tree containing only this value, whereas \texttt{genCons1} constructs from a given search tree a new tree where the function given in the first argument is applied to all values. Similarly, there are also combinators \texttt{genCons2}, \texttt{genCons3} etc. for more than one argument. The combinator \texttt{"|||"} combines two search trees.

If the Curry program containing properties defines a generator operation with the name \texttt{gen\tau}, then CurryCheck uses this generator to test properties with argument type \texttt{\tau}. Hence, if we put the definition of \texttt{genInt} in the Curry program where \texttt{sumUpIsCorrect} is defined, the values to check this property are only non-negative integers. Since these integers are slowly increasing, i.e., the search tree is actually degenerated to a list, we can also use the following definition to obtain a more balanced search tree:

\begin{verbatim}
  genInt = genCons0 0 ||| genCons1 (\n -> 2*(n+1)) genInt
      ||| genCons1 (\n -> 2*n+1) genInt
\end{verbatim}

The library \texttt{SearchTree} defines the structure of search trees as well as operations on search trees, like limiting the depth of a search tree (\texttt{limitSearchTree}) or showing a search tree (\texttt{showSearchTree}). For instance, to structure of the generated search tree up to some depth can be visualized as follows:

\begin{verbatim}
  ...SearchTree> putStr (showSearchTree (limitSearchTree 6 genInt))
\end{verbatim}

If we want to use our own generator only for specific properties, we can do so by introducing a new data type and defining a generator for this data type. For instance, to test only the operation \texttt{sumUpIsCorrect} with non-negative integers, we do not define a generator \texttt{genInt} as above, but define a wrapper type for non-negative integers and a generator for this type:

\begin{verbatim}
  data NonNeg = NonNeg { nonNeg :: Int }
  genNonNeg = genCons1 NonNeg genNN
    where
      genNN = genCons0 0 ||| genCons1 (\n -> 2*(n+1)) genNN
             ||| genCons1 (\n -> 2*n+1) genNN
\end{verbatim}

Now we can either redefine \texttt{sumUpIsCorrect} on this type

\begin{verbatim}
  sumUpIsCorrectOnNonNeg (NonNeg n) = sumUp n ~== n * (n+1) 'div' 2
\end{verbatim}

or we simply reuse the old definition by

\begin{verbatim}
  sumUpIsCorrectOnNonNeg = sumUpIsCorrect . nonNeg
\end{verbatim}

\subsection{Checking Contracts and Specifications}

The expressive power of Curry supports writing high-level specifications as well as efficient implementations for a given problem in the same programming language, as discussed in [4]. If a specification or contract is provided for some function, then CurryCheck automatically generates properties to test this specification or contract.

Following the notation proposed in [4], a \textit{specification} for an operation \texttt{f} is an operation \texttt{f'\text{spec}} of the same type as \texttt{f}. A \textit{contract} consists of a pre- and a postcondition, where the precondition could be omitted. A \textit{precondition} for an operation \texttt{f} of type \texttt{\tau} \rightarrow \texttt{\tau'} is an operation

\begin{verbatim}
  f'pre :: \tau \rightarrow \text{Bool}
\end{verbatim}
whereas a postcondition for \( f \) is an operation

\[
f \rightarrowpost : \tau \rightarrow \tau' \rightarrow \text{Bool}
\]

which relates input and output values (the generalization to operations with more than one argument is straightforward).

As a concrete example, consider again the problem of sorting a list. We can write a postcondition and a specification for a sort operation \( \text{sort} \) and an implementation via quicksort as follows (where \( \text{sorted} \) and \( \text{perm} \) are defined as above):

--- Postcondition: input and output lists should have the same length
\[
\text{sort}'\text{post} \ \text{xs} \ \text{ys} = \text{length} \ \text{xs} == \text{length} \ \text{ys}
\]

--- Specification:
A correct result is a permutation of the input which is sorted.
\[
\text{sort}'\text{spec} : [\text{Int}] \rightarrow [\text{Int}]
\]
\[
\text{sort}'\text{spec} \ \text{xs} | \ \text{ys} == \text{perm} \ \text{xs} \ \&\& \ \text{sorted} \ \text{ys} = \ \text{ys} \ \text{where} \ \text{ys} \ \text{free}
\]

--- An implementation of sort with quicksort:
\[
\text{sort} : [\text{Int}] \rightarrow [\text{Int}]
\]
\[
\text{sort} \ [\] = [\]
\]
\[
\text{sort} \ (\text{x}:\text{xs}) = \text{sort} \ (\text{filter} \ (<\text{x}) \ \text{xs}) \ ++ \ [\text{x}] \ ++ \ \text{sort} \ (\text{filter} \ (\geq\text{x}) \ \text{xs})
\]

If we process this program with CurryCheck, properties to check the specification and postcondition are automatically generated. For instance, a specification is satisfied if it yields the same values as the implementation, and a postcondition is satisfied if each value computed for some input satisfies the postcondition relation between input and output. For our example, CurryCheck generates the following properties (if there are also preconditions for some operation, these preconditions are used to restrict the test cases via the condition operator “==>”):

\[
\text{sort}'\text{satisfiesPostCondition} : [\text{Int}] \rightarrow \text{Prop}
\]
\[
\text{sort}'\text{satisfiesPostCondition} \ \text{x} =
\]
\[
\text{let} \ \text{r} = \text{sort} \ \text{x}
\]
\[
in \ (\text{r} == \text{x}) \Rightarrow \text{always} \ (\text{sort}'\text{post} \ \text{x} \ \text{r})
\]

\[
\text{sort}'\text{satisfiesSpecification} : [\text{Int}] \rightarrow \text{Prop}
\]
\[
\text{sort}'\text{satisfiesSpecification} \ \text{x} = \text{sort} \ \text{x} <~> \text{sort}'\text{spec} \ \text{x}
\]

### 7.4 Checking Usage of Specific Operations

In addition to testing dynamic properties of programs, CurryCheck also examines the source code of the given program for unintended uses of specific operations (these checks can be omitted via the option “--nosource”). Currently, the following source code checks are performed:

- The prelude operation “=:<=” is used to implement functional patterns [2]. It should not be used in source programs to avoid unintended uses. Hence, CurryCheck reports such unintended uses.
- Set functions [3] are used to encapsulate all non-deterministic results of some function in a set structure. Hence, for each top-level function \( f \) of arity \( n \), the corresponding set function can
be expressed in Curry (via operations defined in the module SetFunctions, see Section A.2.34) by the application “\(\text{set} \, n \, f\)” (this application is used in order to extend the syntax of Curry with a specific notation for set functions). However, it is not intended to apply the operator “\(\text{set} \, n\)” to lambda abstractions, locally defined operations or operations with an arity different from \(n\). Hence, CurryCheck reports such unintended uses of set functions.
8 CurryBrowser: A Tool for Analyzing and Browsing Curry Programs

CurryBrowser is a tool to browse through the modules and operations of a Curry application, show them in various formats, and analyze their properties. Moreover, it is constructed in a way so that new analyzers can easily be connected to CurryBrowser. A detailed description of the ideas behind this tool can be found in [19, 20].

8.1 Installation

The current implementation of CurryBrowser is a package managed by the Curry Package Manager CPM (see also Section 6). Thus, to install the newest version of CurryBrowser, use the following commands:

```
> cypm update
> cypm install currybrowse
```

This downloads the newest package, compiles it, and places the executable `curry-browse` into the directory `$HOME/.cpm/bin`. Hence it is recommended to add this directory to your path in order to execute CurryBrowser as described below.

8.2 Basic Usage

When CurryBrowser is installed as described above, it can be started in two ways:

- In the KiCS2 environment after loading the module `mod` and typing the command `:browse`.
- As a shell command (provided that `$HOME/.cpm/bin` is in your path): `curry-browse mod`

Here, “mod” is the name of the main module of a Curry application. After the start, CurryBrowser loads the interfaces of the main module and all imported modules before a GUI is created for interactive browsing.

To get an impression of the use of CurryBrowser, Figure 1 shows a snapshot of its use on a particular application (here: the implementation of CurryBrowser). The upper list box in the left column shows the modules and their imports in order to browse through the modules of an application. Similarly to directory browsers, the list of imported modules of a module can be opened or closed by clicking. After selecting a module in the list of modules, its source code, interface, or various other formats of the module can be shown in the main (right) text area. For instance, one can show pretty-printed versions of the intermediate flat programs (see below) in order to see how local function definitions are translated by lambda lifting [27] or pattern matching is translated into case expressions [15, 32]. Since Curry is a language with parametric polymorphism and type inference, programmers often omit the type signatures when defining functions. Therefore, one can also view (and store) the selected module as source code where missing type signatures are added.

---

5 Although CurryBrowser is implemented in Curry, some functionalities of it require an installed graph visualization tool (dot http://www.graphviz.org/), otherwise they have no effect.
Below the list box for selecting modules, there is a menu ("Analyze selected module") to analyze all functions of the currently selected module at once. This is useful to spot some functions of a module that could be problematic in some application contexts, like functions that are impure (i.e., the result depends on the evaluation time) or partially defined (i.e., not evaluable on all ground terms). If such an analysis is selected, the names of all functions are shown in the lower list box of the left column (the "function list") with prefixes indicating the properties of the individual functions.

The function list box can be also filled with functions via the menu "Select functions". For instance, all functions or only the exported functions defined in the currently selected module can be shown there, or all functions from different modules that are directly or indirectly called from a currently selected function. This list box is central to focus on a function in the source code of some module or to analyze some function, i.e., showing their properties. In order to focus on a function, it is sufficient to check the "focus on code" button. To analyze an individually selected function, one can select an analysis from the list of available program analyses (through the menu "Select analysis"). In this case, the analysis results are either shown in the text box below the main text area or visualized by separate tools, e.g., by a graph drawing tool for visualizing call graphs. Some analyses are local, i.e., they need only to consider the local definition of this function (e.g., "Calls
directly,” “Overlapping rules,” “Pattern completeness”), where other analyses are global, i.e., they consider the definitions of all functions directly or indirectly called by this function (e.g., “Depends on,” “Solution complete,” “Set-valued”). Finally, there are a few additional tools integrated into CurryBrowser, for instance, to visualize the import relation between all modules as a dependency graph. These tools are available through the “Tools” menu.

More details about the use of CurryBrowser and all built-in analyses are available through the “Help” menu of CurryBrowser.
9 curry-doc: A Documentation Generator for Curry Programs

CurryDoc is a tool in the KiCS2 distribution that generates the documentation for a Curry program (i.e., the main module and all its imported modules) in HTML format. The generated HTML pages contain information about all data types and functions exported by a module as well as links between the different entities. Furthermore, some information about the definitional status of functions (like rigid, flexible, external, complete, or overlapping definitions) are provided and combined with documentation comments provided by the programmer.

9.1 Installation

The current implementation of CurryDoc is a package managed by the Curry Package Manager CPM (see also Section 6). Thus, to install the newest version of CurryDoc, use the following commands:

```
> cypm update
> cypm install currydoc
```

This downloads the newest package, compiles it, and places the executable curry-doc into the directory `$HOME/.cpm/bin`. Hence it is recommended to add this directory to your path in order to execute CurryDoc as described below.

9.2 Documentation Comments

A documentation comment starts at the beginning of a line with “---” (also in literate programs!). All documentation comments immediately before a definition of a datatype or (top-level) function are kept together. The documentation comments for the complete module occur before the first “module” or “import” line in the module. The comments can also contain several special tags. These tags must be the first thing on its line (in the documentation comment) and continues until the next tag is encountered or until the end of the comment. The following tags are recognized:

@author comment
- Specifies the author of a module (only reasonable in module comments).

@version comment
- Specifies the version of a module (only reasonable in module comments).

@cons id comment
- A comment for the constructor `id` of a datatype (only reasonable in datatype comments).

@param id comment
- A comment for function parameter `id` (only reasonable in function comments). Due to pattern matching, this need not be the name of a parameter given in the declaration of the function but all parameters for this functions must be commented in left-to-right order (if they are commented at all).

\footnote{The documentation tool recognizes this association from the first identifier in a program line. If one wants to add a documentation comment to the definition of a function which is an infix operator, the first line of the operator definition should be a type definition, otherwise the documentation comment is not recognized.}

42
A comment for the return value of a function (only reasonable in function comments).

The comment of a documented entity can be any string in Markdown’s syntax (the currently supported set of elements is described in detail in the appendix). For instance, it can contain Markdown annotations for emphasizing elements (e.g., _verb_), strong elements (e.g., **important**), code elements (e.g., ‘3+4’), code blocks (lines prefixed by four blanks), unordered lists (lines prefixed by “ _ ”), ordered lists (lines prefixed by blanks followed by a digit and a dot), quotations (lines prefixed by “ > ”), and web links of the form “<http://...>” or “[link text](http://...)”. If the Markdown syntax should not be used, one could run CurryDoc with the parameter “--nomarkdown”.

The comments can also contain markups in HTML format so that special characters like ‘<’ must be quoted (e.g., “&lt;”). However, header tags like <h1> should not be used since the structuring is generated by CurryDoc. In addition to Markdown or HTML markups, one can also mark references to names of operations or data types in Curry programs which are translated into links inside the generated HTML documentation. Such references have to be enclosed in single quotes. For instance, the text ’conc’ refers to the Curry operation conc inside the current module whereas the text ’Prelude.reverse’ refers to the operation reverse of the module Prelude. If one wants to write single quotes without this specific meaning, one can escape them with a backslash:

--- This is a comment without a ‘reference’.

To simplify the writing of documentation comments, such escaping is only necessary for single words, i.e., if the text inside quotes has not the syntax of an identifier, the escaping can be omitted, as in

--- This isn’t a reference.

The following example text shows a Curry program with some documentation comments:

--- This is an example module.
--- @author Michael Hanus
--- @version 0.1

module Example where

--- The function ‘conc’ concatenates two lists.
--- @param xs - the first list
--- @param ys - the second list
--- @return a list containing all elements of ‘xs’ and ‘ys’
conc [] ys = ys
conc (x:xs) ys = x : conc xs ys
-- this comment will not be included in the documentation

--- The function ‘last’ computes the last element of a given list.
--- It is based on the operation ‘conc’ to concatenate two lists.
--- @param xs - the given input list
--- @return last element of the input list
last xs | conc ys [x] =:= xs = x  where x,ys free

--- This data type defines _polymorphic_ trees.
9.3 Generating Documentation

To generate the documentation, execute the command

curry-doc Example

This command creates the directory DOC_Example (if it does not exist) and puts all HTML documentation files for the main program module Example and all its imported modules in this directory together with a main index file index.html. If one prefers another directory for the documentation files, one can also execute the command

curry-doc docdir Example

where docdir is the directory for the documentation files.

In order to generate the common documentation for large collections of Curry modules (e.g., the libraries contained in the KiCS2 distribution), one can call curry-doc with the following options:

curry-doc --noindexhtml docdir Mod: This command generates the documentation for module Mod in the directory docdir without the index pages (i.e., main index page and index pages for all functions and constructors defined in Mod and its imported modules).

curry-doc --onlyindexhtml docdir Mod1 Mod2 ...Modn: This command generates only the index pages (i.e., a main index page and index pages for all functions and constructors defined in the modules Mod1, Mod2, ..., Modn and their imported modules) in the directory docdir.
10 curry-style: A Style Checker for Curry Programs

CASC is a tool to check the formatting style of Curry programs. The preferred style for writing Curry programs, which is partially checked by this tool, is described in a separate web page\(^7\). Currently, CASC only checks a few formatting rules, like line lengths or indentation of if-then-else, but the kind of checks performed by CASC will be extended in the future.

10.1 Installation

The current implementation of CASC is a package managed by the Curry Package Manager CPM (see also Section 6). Thus, to install the newest version of CASC, use the following commands:

```
> cypm update
> cypm install casc
```

This downloads the newest package, compiles it, and places the executable `curry-style` into the directory `HOME/.cpm/bin`. Hence it is recommended to add this directory to your path in order to execute CASC as described below.

10.2 Basic Usage

To check the style of some Curry program stored in the file `prog.curry`, one can invoke the style checker by the command

```
curry-style prog
```

After processing the program, a list of all positions with stylistic errors is printed.

10.3 Configuration

CASC can be configured so that not all stylistic rules are checked. For this purpose, one should copy the global configuration file `cascrc` of CASC, which is stored in the main directory of the package,\(^8\) into the home directory under the name “.cascrc”. Then one can configure this file according to your own preferences, which are described in this file.

\(^7\) [http://www.informatik.uni-kiel.de/~pakcs/CurryStyleGuide.html](http://www.informatik.uni-kiel.de/~pakcs/CurryStyleGuide.html)

\(^8\) If you installed CASC as described above, the downloaded package is located in the directory `HOME/.cpm/bin_packages/casc`.

11 CurryVerify: A Tool to Support the Verification of Curry Programs

CurryVerify is a tool that supports the verification of Curry programs with the help of other theorem provers or proof assistants. Basically, CurryVerify extends CurryCheck (see Section 7), which tests given properties of a program, by the possibility to verify these properties. For this purpose, CurryVerify translates properties into the input language of other theorem provers or proof assistants. This is done by collecting all operations directly or indirectly involved in a given property and translating them together with the given property.

Currently, only Agda [30] is supported as a target language for verification (but more target languages may be supported in future releases). The basic schemes to translate Curry programs into Agda programs are presented in [7]. That paper also describes the limitations of this approach. Since Curry is a quite rich programming language, not all constructs of Curry are currently supported in the translation process (e.g., no case expressions, local definitions, list comprehensions, do notations, etc). Only a kernel language, where the involved rules correspond to a term rewriting system, are translated into Agda. However, these limitations might be relaxed in future releases. Hence, the current tool should be considered as a first prototypical approach to support the verification of Curry programs.

11.1 Installation

The current implementation of CurryVerify is a package managed by the Curry Package Manager CPM (see also Section 6). Thus, to install the newest version of CurryVerify, use the following commands:

```bash
> cypm update
> cypm install verify
```

This downloads the newest package, compiles it, and places the executable `curry-verify` into the directory `$HOME/.cpm/bin`. Hence it is recommended to add this directory to your path in order to execute CurryVerify as described below.

11.2 Basic Usage

To translate the properties of a Curry program stored in the file `prog.curry` into Agda, one can invoke the command

```
curry-verify prog
```

This generates for each property `p` in module `prog` an Agda program “`TO-PROVE-p.agda`”. If one completes the proof obligation in this file, the completed file should be renamed into “`PROOF-p.agda`”. This has the effect that CurryCheck does not test this property again but trusts the proof and use this knowledge to simplify other tests.

As a concrete example, consider the following Curry module `Double`, shown in Figure 2, which uses the Peano representation of natural numbers (module `Nat`) to define an operation to double the value of a number, a non-deterministic operation `coin` which returns its argument or its incremented
module Double(double, coin, even) where

import Nat
import Test.Prop

double x = add x x
coin x = x ? S x

even Z = True
even (S Z) = False
even (S (S n)) = even n

evenDoubleCoin x = always (even (double (coin x)))

Figure 2: Curry program Double.curry

argument, and a predicate to test whether a number is even. Furthermore, it contains a property
specifying that doubling the coin of a number is always even.

In order to prove the correctness of this property, we translate it into an Agda program by
executing

> curry-verify Double

... 
Agda module 'TO-PROVE-evendoublecoin.agda' written.
If you completed the proof, rename it to 'PROOF-evendoublecoin.agda'.

The Curry program is translated with the default scheme (see further options below) based on the
"planned choice" scheme, described in [7]. The result of this translation is shown in Figure 3.

The Agda program contains all operations involved in the property and the property itself.
Non-deterministic operations, like coin, have an additional additional argument of the abstract
type Choice that represents the plan to execute some non-deterministic branch of the program. By
proving the property for all possible branches as correct, it universally holds.

In our example, the proof is quite easy. First, we prove that the addition of a number to itself
is always even (lemma even-add-x-x, which uses an auxiliary lemma add-suc). Then, the property
is an immediate consequence of this lemma:

add-suc : ∀ (x y : N) → add x (suc y) ≡ suc (add x y)
add-suc zero y = refl
add-suc (suc x) y rewrite add-suc x y = refl

even-add-x-x : ∀ (x : N) → even (add x x) ≡ tt
even-add-x-x zero = refl
even-add-x-x (suc x) rewrite add-suc x x | even-add-x-x x = refl

evenDoubleCoin : (c1 : Choice) → (x : N) → (even (double (coin c1 x))) ≡ tt
evenDoubleCoin c1 x rewrite even-add-x-x (coin c1 x) = refl
As the proof is complete, we rename this Agda program into PROOF-evendoublecoin.agda so that the proof can be used by further invocations of CurryCheck.

11.3 Options

The command curry-verify can be parameterized with various options. The available options can also be shown by executing

    curry-verify --help

The options are briefly described in the following.

-h, -?, --help These options trigger the output of usage information.

-q, --quiet Run quietly and produce no informative output. However, the exit code will be non-zero if some translation error occurs.

-v[n], --verbosity [=n] Set the verbosity level to an optional value. The verbosity level 0 is the same as option -q. The default verbosity level 1 shows the translation progress. The verbosity level 2 (which is the same as omitting the level) shows also the generated (Agda) program. The verbosity level 3 shows also more details about the translation process.

-n, --nostore Do not store the translated program in a file but show it only.

-p p, --property= p As a default, all properties occurring in the source program are translated. If this option is provided, only property p is translated.

-t t, --target=t Define the target language of the translation. Currently, only t = Agda is supported, which is also the default.

-s s, --scheme=s Define the translation scheme used to represent Curry programs in the target language.

For the target Agda, the following schemes are supported:

choice Use the “planned choice” scheme, see [7] (this is the default). In this scheme, the choices made in a non-deterministic computation are abstracted by passing a parameter for these choices.

nondet Use the “set of values” scheme, see [7], where non-deterministic values are represented in a tree structure.
-- Agda program using the Iowa Agda library

open import bool

module TO-PROVE-evendoublecoin
  (Choice : Set)
  (choose : Choice → B)
  (lchoice : Choice → Choice)
  (rchoice : Choice → Choice)
where

open import eq
open import nat
open import list
open import maybe

---------------------------------------------------------------------------
-- Translated Curry operations:

add : N → N → N
add zero x = x
add (suc y) z = suc (add y z)

coin : Choice → N → N
coin c1 x = if choose c1 then x else suc x

double : N → N
double x = add x x

even : N → B
even zero = tt
even (suc zero) = ff
even (suc (suc x)) = even x

---------------------------------------------------------------------------

evendoublecoin : (c1 : Choice) → (x : N) → (even (double (coin c1 x))) ≡ tt
evendoublecoin c1 x = ?

12 CurryPP: A Preprocessor for Curry Programs

The Curry preprocessor “currypp” implements various transformations on Curry source programs. It supports some experimental language extensions that might become part of the standard parser of Curry in some future version.

Currently, the Curry preprocessor supports the following extensions that will be described below in more detail:

**Integrated code**: This extension allows to integrate code written in some other language into Curry programs, like regular expressions, format specifications ("printf"), HTML and XML code.

**Default rules**: If this feature is used, one can add a default rule to operations defined in a Curry module. This provides a similar power than sequential rules but with a better operational behavior. The idea of default rules is described in [6].

**Contracts**: If this feature is used, the Curry preprocessor looks for contracts (i.e., specification, pre- and postconditions) occurring in a Curry module and adds them as assertions that are checked during the execution of the program. Currently, only strict assertion checking is supported which might change the operational behavior of the program. The idea and usage of contracts is described in [4].

12.1 Installation

The current implementation of Curry preprocessor is a package managed by the Curry Package Manager CPM (see also Section 6). Thus, to install the newest version of currypp, use the following commands:

```
> cypm update
> cypm install currypp
```

This downloads the newest package, compiles it, and places the executable currypp into the directory `$HOME/.cpm/bin`. Hence one should add this directory to the path in order to use the Curry preprocessor as described below.

12.2 Basic Usage

In order to apply the preprocessor when loading a Curry source program into KiCS2, one has to add an option line at the beginning of the source program. For instance, in order to use default rules in a Curry program, one has to put the line

```
{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=defaultrules #-}
```

at the beginning of the program. This option tells the KiCS2 front end to process the Curry source program with the program currypp before actually parsing the source text.

The option “defaultrules” has to be replaced by “contracts” to enable dynamic contract checking. To support integrated code, one has to set the option “foreigncode” (which can also be combined with “defaultrules”). If one wants to see the result of the transformation, one can also
set the option "-o". This has the effect that the transformed source program is stored in the file
Prog.curry.CURRYPP if the name of the original program is Prog.curry.

For instance, in order to use integrated code and default rules in a module and store the trans-
formed program, one has to put the line

```{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=foreigncode --optF=defaultrules --optF=-o #-}```
at the beginning of the program. If the options about the kind of preprocessing is omitted, all kinds
of preprocessing are applied. Thus, the preprocessor directive

```{-# OPTIONS_CYMAKE -F --pgmF=currypp #-}```
is equivalent to

```{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=foreigncode --optF=defaultrules --optF=contracts #-}```

12.3 Integrated Code

Integrated code is enclosed in at least two back ticks and ticks in a Curry program. The number
of starting back ticks and ending ticks must always be identical. After the initial back ticks, there
must be an identifier specifying the kind of integrated code, e.g., `regex` or `html` (see below). For
instance, if one uses regular expressions (see below for more details), the following expressions are
valid in source programs:

```match "regex (a|(bc*))+"
mismatch "regex aba*c"```
The Curry preprocessor transforms these code pieces into regular Curry expressions. For this
purpose, the program containing this code must start with the preprocessing directive

```{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=foreigncode #-}```
The next sections describe the currently supported foreign languages.

12.3.1 Regular Expressions

In order to match strings against regular expressions, i.e., to check whether a string is contained in
the language generated by a regular expression, one can specify regular expression similar to POSIX.
The foreign regular expression code must be marked by "regex". Since this code is transformed into
operations of the KiCS2 library RegExp, this library must be imported.

For instance, the following module defines a predicate to check whether a string is a valid
identifier:

```{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=foreigncode #-}```

```import RegExp

isID :: String → Bool
isID = match "regex [a-zA-Z][a-zA-Z0-9_]*"```
12.3.2 Format Specifications

In order to format numerical and other data as strings, one can specify the desired format with foreign code marked by “format”. In this case, one can write a format specification, similarly to the printf statement of C, followed by a comma-separated list of arguments. This format specification is transformed into operations of the KiCS2 library Format so that it must be imported. For instance, the following program defines an operation that formats a string, an integer (with leading sign and zeros), and a float with leading sign and precision 3:

```haskell
{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=foreigncode #-}

import Format

showSIF :: String → Int → Float → String
showSIF s i f = "format "Name: %s | %+.5i | %+6.3f",s,i,f"

main = putStrLn $ showSIF "Curry" 42 3.14159
```

Thus, the execution of `main` will print the line

Name: Curry | +00042 | +3.142

Instead of “format”, one can also write a format specification with `printf`. In this case, the formatted string is printed with `putStr`. Hence, we can rewrite our previous definitions as follows:

```haskell
{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=foreigncode #-}

import Format

showSIF :: String → Int → Float → IO ()
showSIF s i f = "printf "Name: %s | %+.5i | %+6.3f\n",s,i,f"

main = putStrLn $ showSIF "Curry" 42 3.14159
```

12.3.3 HTML Code

The foreign language tag “html” introduces a notation for HTML expressions (see KiCS2 library HTML) with the standard HTML syntax extended by a layout rule so that closing tags can be omitted. In order to include strings computed by Curry expressions into these HTML syntax, these Curry expressions must be enclosed in curly brackets. The following example program shows its use:

```haskell
{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=foreigncode #-}

import HTML

htmlPage :: String → [HtmlExp]
htmlPage name = "html
  <html>
    <head>
      <title>Simple Test
    <body>
      <h1>Hello {name}!</h1>
    <p>
```
Bye!
<p>Bye!
<h2>{reverse name}
Bye!''

If a Curry expression computes an HTML expression, i.e., it is of type HtmlExp instead of String, it can be integrated into the HTML syntax by double curly brackets. The following simple example, taken from [18], shows the use of this feature:

{-# OPTIONS_CYMAME -F --pgmF=currypp --optF=foreigncode #-}

import HTML

main :: IO HtmlForm
main = return $ form "Question" $
  'html
    Enter a string: {{textfield tref ""}}
  <hr>
  {{button "Reverse string" revhandler}}
  {{button "Duplicate string" duphandler}}''

where
  tref free

  revhandler env = return $ form "Answer" $
  'html <h1>Reversed input: {reverse (env tref)}''

  duphandler env = return $ form "Answer" $
  'html
    <h1>
      Duplicated input:
      {env tref ++ env tref}''

12.3.4 XML Expressions

The foreign language tag "xml" introduces a notation for XML expressions (see KiCS2 library XML). The syntax is similar to the language tag "html", i.e., the use of the layout rule avoids closing tags and Curry expressions evaluating to strings (String) and XML expressions (XmlExp) can be included by enclosing them in curly and double curly brackets, respectively. The following example program shows its use:

{-# OPTIONS_CYMAME -F --pgmF=currypp --optF=foreigncode #-}

import HTML

import XML

main :: IO ()
main = putStrLn $ showXmlDoc $ head 'xml
12.4 SQL Statements

The Curry preprocessor also supports SQL statements in their standard syntax as integrated code. In order to ensure a type-safe integration of SQL statements in Curry programs, SQL queries are type-checked in order to determine their result type and ensure that the entities used in the queries are type correct with the underlying relational database. For this purpose, SQL statements are integrated code require a specification of the database model in form of entity-relationship (ER) model. From this description, a set of Curry data types are generated which are used to represent entities in the Curry program (see Section 12.4.1). The Curry preprocessor uses this information to type check the SQL statements and replace them by type-safe access methods to the database. In the following, we sketch the use of SQL statements as integrated code. A detailed description of the ideas behind this technique can be found in [23]. Currently, only SQLite databases are supported.

12.4.1 ER Specifications

The structure of the data stored in underlying database must be described as an entity-relationship model. Such a description consists of

1. a list of entities where each entity has attributes,
2. a list of relationships between entities which have cardinality constraints that must be satisfied in each valid state of the database.

Entity-relationships models are often visualized as entity-relationship diagrams (ERDs). Figure 4 shows an ERD which we use in the following examples.

Instead of requiring the use of some graphical ER modeling tool, ERDs must be specified in textual form as a Curry data term, see also [10]. In this representation, an ERD has a name, which is also used as the module name of the generated Curry code, lists of entities and relationships:

```
data ERD = ERD String [Entity] [Relationship]
```

Each entity consists of a name and a list of attributes, where each attribute has a name, a domain, and specifications about its key and null value property:
data Entity = Entity String [Attribute]

data Attribute = Attribute String Domain Key Null

data Key = NoKey | PKey | Unique

type Null = Bool

data Domain = IntDom (Maybe Int) | FloatDom (Maybe Float) | CharDom (Maybe Char) | StringDom (Maybe String) | BoolDom (Maybe Bool) | DateDom (Maybe ClockTime) | UserDefined String (Maybe String) | KeyDom String -- later used for foreign keys

Figure 4: A simple entity-relationship diagram for university lectures [23]
Thus, each attribute is part of a primary key (PKey), unique (Unique), or not a key (NoKey). Furthermore, it is allowed that specific attributes can have null values, i.e., can be undefined. The domain of each attribute is one of the standard domains or some user-defined type. In the latter case, the first argument of the constructor UserDefined is the qualified type name used in the Curry application program. For each kind of domain, one can also have a default value (modeled by the Maybe type). The constructor KeyDom is not necessary to represent ERDs but it is internally used to transform complex ERDs into relational database schemas.

Finally, each relationship has a name and a list of connections to entities (REnd), where each connection has the name of the connected entity, the role name of this connection, and its cardinality as arguments:

```haskell
data Relationship = Relationship String [REnd]

data REnd = REnd String String Cardinality

data Cardinality = Exactly Int | Between Int MaxValue

data MaxValue = Max Int | Infinite
```

The cardinality is either a fixed integer or a range between two integers (where Infinite as the upper bound represents an arbitrary cardinality). For instance, the simple-complex (1:n) relationship Teaching in Fig.4 can be represented by the term

```
Relationship "Teaching"
    [REnd "Lecturer" "taught_by" (Exactly 1),
     REnd "Lecture" "teaches" (Between 0 Infinite)]
```

The KiCS2 library Database.ERD contains the ER datatypes described above. Thus, the specification of the conceptual database model must be a data term of type Database.ERD.ERD. Figure 5 on (page 61) shows the complete ER data term specification corresponding to the ERD of Fig. 4.

Such a data term specification should be stored in Curry program file as an (exported!) top-level operation type ERD. If our example term is defined as a constant in the Curry program UniERD.curry, then one has to use the tool “erd2curry” (see Sect. 15) to process the ER model so that it can be used in SQL statements. This tool is invoked with the parameter “--cdbi”, the (preferably absolute) file name of the SQLite database, and the name of the Curry program containing the ER specification. If the SQLite database file does not exist, it will be initialized by the tool. In our example, we execute the following command (provided that the tool erd2curry is already installed, see Sect. 15):

```
> erd2curry --db 'pwd'/Uni.db --cdbi UniERD.curry
```

This initializes the SQLite database Uni.db and performs the following steps:

1. The ER model is transformed into tables of a relational database, i.e., the relations of the ER model are either represented by adding foreign keys to entities (in case of (0/1:1) or (0/1:n) relations) or by new entities with the corresponding relations (in case of complex (n:m) relations).

2. A new Curry module Uni.CDBI is generated. It contains the definitions of entities and relationships as Curry data types. Since entities are uniquely identified via a database key, each
entity definition has, in addition to its attributes, this key as the first argument. For instance, the following definitions are generated for our university ERD (among many others):

```haskell
data StudentID = StudentID Int

data Student = Student StudentID String String Int String Int

-- Representation of n:m relationship Participation:
data Participation = Participation StudentID LectureID
```

Note that the two typed foreign key columns (StudentID, LectureID) ensures a type-safe handling of foreign-key constraints. These entity descriptions are relevant for SQL queries since some queries (e.g., those that do not project on particular database columns) return lists of such entities. Moreover, the generated module contains useful getter and setter functions for each entity. Other generated operations, like entity description and definitions of their columns, are not relevant for the programming but only used for the translation of SQL statements.

3. Finally, an info file Uni.SQLCODE.info is created. It contains information about all entities, attributes and their types, and relationships. This file is used by the SQL parser and translator of the Curry preprocessor to type check the SQL statements and generate appropriate Curry library calls.

### 12.4.2 SQL Statements as Integrated Code

After specifying and processing the ER model of the database, one can write SQL statement in their standard syntax as integrated code (marked by the prefix “sql”) in Curry programs. For instance, to retrieve all students from the database, one can define the following SQL query:

```haskell
allStudents :: IO (SQLResult [Student])
allStudents = "sql Select * From Student;"
```

Since database accesses might produce errors, the result of SQL statements is always of type “SQLResult τ”, where SQLResult is a type synonym defined in the KiCS2 library Database.CDBI.Connection:

```haskell
type SQLResult a = Either DBError a
```

This library defines also an operation

```haskell
fromSQLResult :: SQLResult a → a
```

which returns the retrieved database value or raises a run-time error. Hence, if one does not want to check the occurrence of database errors immediately, one can also define the above query as follows:

```haskell
allStudents :: IO [Student]
allStudents = liftIO fromSQLResult "sql Select * From Student;"
```

In order to select students with an age between 20 and 25, one can put a condition as usual:

```haskell
youngStudents :: IO (SQLResult [Student])
youngStudents = "sql Select * From Student
   Where Age between 18 and 21;"
```
Usually, one wants to parameterize queries over some values computed by the context of the Curry program. Therefore, one can embed Curry expressions instead of concrete values in SQL statements by enclosing them in curly brackets:

```haskell
studAgeBetween :: Int → Int → IO (SQLResult [Student])
studAgeBetween min max =
  "sql Select * From Student
   Where Age between {min} and {max};""
```

Instead of retrieving complete entities (database tables), one can also project on some attributes (database columns) and one can also order them with the usual “Order By” clause:

```haskell
studAgeBetween :: Int → Int → IO (SQLResult [(String,Int)])
studAgeBetween min max =
  "sql Select Name, Age
   From Student Where Age between {min} and {max}
   Order By Name Desc;""
```

In addition to the usual SQL syntax, one can also write conditions on relationships between entities. For instance, the following code will be accepted:

```haskell
studGoodGrades :: IO (SQLResult [(String, Float)])
studGoodGrades = "sql Select Distinct s.Name, r.Grade
   From Student as s, Result as r
   Where Satisfies s has_a r And r.Grade < 2.0;"
```

This query retrieves a list of pairs containing the names and grades of students having a grade better than 2.0. This query is beyond pure SQL since it also includes a condition on the relation `has_a` specified in the ER model (“Satisfies s has_a r”).

The complete SQL syntax supported by the Curry preprocessor is shown in Appendix C. More details about the implementation of this SQL translator can be found in [23, 28].

### 12.5 Default Rules

An alternative to sequential rules are default rules, i.e., these two options cannot be simultaneously used. Default rules are activated by the preprocessor option “defaultrules”. In this case, one can add to each operation a default rule. A default rule for a function `f` is defined as a rule defining the operation “`f default`” (this mechanism avoids any language extension for default rules). A default rule is applied only if no “standard” rule is applicable, either because the left-hand sides' pattern do not match or the conditions are not satisfiable. The idea and detailed semantics of default rules are described in [6].

Default rules are preferable over the sequential rule selection strategy since they have a better operational behavior. This is due to the fact that the test for the application of default rules is done with the same (sometimes optimal) strategy than the selection of standard rules. Moreover, default rules provide a similar power than sequential rules, i.e., they can be applied if the standard rules have complex (functional) patterns or complex conditions.

As a simple example, we show the implementation of the previous example for sequential rules with a default rule:

```haskell
{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=defaultrules #-}
```
Default rules are often a good replacement for “negation as failure” used in logic programming. For instance, the following program defines a solution to the $n$-queens puzzle, where the default rule is useful since it is easier to characterize the unsafe positions of the queens on the chessboard (see the first rule of \texttt{safe}):\footnote{\texttt{safe}}

\begin{verbatim}
{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=defaultrules #-}

import Combinatorial(permute)
import Integer(abs)

-- A placement is safe if two queens are not in a same diagonal:
safe (_++[x]++ys++[z]++_) | abs (x-z) == length ys + 1 = failed
safe’default xs = xs

-- A solution to the $n$-queens puzzle is a safe permutation:
queens :: Int \rightarrow [Int]
queens n = safe (permute [1..n])
\end{verbatim}

### 12.6 Contracts

Contracts are annotations in Curry program to specify the intended meaning and use of operations by other operations or predicates expressed in Curry. The idea of using contracts for the development of reliable software is discussed in [4]. The Curry preprocessor supports dynamic contract checking by transforming contracts, i.e., specifications and pre-/postconditions, into assertions that are checked during the execution of a program. If some contract is violated, the program terminates with an error.

The transformation of contracts into assertions is described in [4]. Note that only strict assertion checking is supported at the moment. Strict assertion checking might change the operational behavior of the program. The notation of contracts has been shortly introduced in Section 7.3. To transform such contracts into assertions, one has to use the option “contracts” for the preprocessor.

As a concrete example, consider an implementation of quicksort with a postcondition and a specification as shown in Section 7.3 (where the code for \texttt{sorted} and \texttt{perm} is not shown here):\footnote{\texttt{contracts}}

\begin{verbatim}
{-# OPTIONS_CYMAKE -F --pgmF=currypp --optF=contracts #-}

-- Trivial precondition:
sort’pre xs = length xs >= 0

-- Postcondition: input and output lists should have the same length
sort’post xs ys = length xs == length ys

-- Specification:
\end{verbatim}
-- A correct result is a permutation of the input which is sorted.
sort'spec :: [Int] → [Int]
sort'spec xs | ys == perm xs && sorted ys = ys where ys free

-- A buggy implementation of quicksort:
sort :: [Int] → [Int]
sort [] = []
sort (x:xs) = sort (filter (<x) xs) ++ [x] ++ sort (filter (>x) xs)

If this program is executed, the generated assertions report a contract violation for some inputs:

Quicksort> sort [3,1,4,2,1]
Postcondition of 'sort' (module Quicksort, line 27) violated for:
[1,2,1] → [1,2]

ERROR: Execution aborted due to contract violation!

Figure 5: The ER data term specification of Fig. 4
13 runcurry: Running Curry Programs

runcurry is a simple tool to support the execution of Curry programs without explicitly invoking the interactive environment. Hence, it can be useful to write short scripts in Curry intended for direct execution. The Curry program must always contain the definition of an operation `main` of type `IO ()`. The execution of the program consists of the evaluation of this operation.

13.1 Installation

The implementation of runcurry is a package managed by the Curry Package Manager CPM. Thus, to install the newest version of runcurry, use the following commands:

```
> cypm update
> cypm install runcurry
```

This downloads the newest package, compiles it, and places the executable runcurry into the directory `$HOME/.cpm/bin`. Hence it is recommended to add this directory to your path in order to use runcurry as described below.

13.2 Using runcurry

Basically, the command runcurry supports three modes of operation:

- One can execute a Curry program whose file name is provided as an argument when runcurry is called. In this case, the suffix (".curry" or ".lcurry") must be present and cannot be dropped. One can write additional commands for the interactive environment, typically settings of some options, before the Curry program name. All arguments after the Curry program name are passed as run-time arguments. For instance, consider the following program stored in the file ShowArgs.curry:

  ```
  import System(getArgs)
  main = getArgs >>= print
  ```

  This program can be executed by the shell command

  ```
  > runcurry ShowArgs.curry
  Hello World!
  ```

  which produces the output

  ```
  ["Hello","World!"]
  ```

- One can also execute a Curry program whose program text comes from the standard input. Thus, one can either “pipe” the program text into this command or type the program text on the keyboard. For instance, if we type

  ```
  > runcurry
  main = putStrLn . unlines . map show . take 8 $ [1..]
  ```

  (followed by the end-of-file marker Ctrl-D), the output
is produced.

- One can also write the program text in a script file to be executed like a shell script. In this case, the script must start with the line

```
#!/usr/bin/env runcurry
```

followed by the source text of the Curry program. For instance, we can write a simple Curry script to count the number of code lines in a Curry program by removing all blank and comment lines and counting the remaining lines:

```
#!/usr/bin/env runcurry

import Char(isSpace)
import System(getArgs)

-- count number of program lines in a file:
countCLines :: String → IO Int
countCLines f =
  readFile f >>=
  return . length . filter (not . isEmptyLine) . map stripSpaces . lines
  where
    stripSpaces = reverse . dropWhile isSpace . reverse . dropWhile isSpace

    isEmptyLine []       = True
    isEmptyLine [ ]      = False
    isEmptyLine (c1:c2:_) = c1=='-' && c2=='-'

-- The main program reads Curry file names from arguments:
main = do
  args <- getArgs
  mapIO_ (\f → do ls ← countCLines f
                putStrLn $ "Stripped lines of file "+f++": " ++ show ls)
            args
```

If this script is stored in the (executable) file “codelines.sh”, we can count the code lines of the file Prog.curry by the shell command

```
> ./codelines.sh Prog.curry
```

When this command is executed, the command runcurry compiles the program and evaluates the expression main. Since the compilation might take some time in more complex scripts,
one can also save the result of the compilation in a binary file. To obtain this behavior, one has to insert the line

`#jit`

in the script file, e.g., in the second line. With this option, a binary of the compiled program is saved (in the same directory as the script). Now, when the same script is executed the next time, the stored binary file is executed (provided that it is still newer than the script file itself, otherwise it will be recompiled). This feature combines easy scripting with Curry together with fast execution.
# 14 CASS: A Generic Curry Analysis Server System

CASS (Curry Analysis Server System) is a tool for the analysis of Curry programs. CASS is generic so that various kinds of analyses (e.g., groundness, non-determinism, demanded arguments) can be easily integrated into CASS. In order to analyze larger applications consisting of dozens or hundreds of modules, CASS supports a modular and incremental analysis of programs. Moreover, it can be used by different programming tools, like documentation generators, analysis environments, program optimizers, as well as Eclipse-based development environments. For this purpose, CASS can also be invoked as a server system to get a language-independent access to its functionality. CASS is completely implemented Curry as a master/worker architecture to exploit parallel or distributed execution environments. The general design and architecture of CASS is described in [24]. In the following, CASS is presented from a perspective of a programmer who is interested to analyze Curry programs.

## 14.1 Installation

The current implementation of CASS is a package managed by the Curry Package Manager CPM. Thus, to install the newest version of CASS, use the following commands:

```
> cypm update
> cypm install cass
```

This downloads the newest package, compiles it, and places the executable `cass` into the directory `$HOME/.cpm/bin`. Hence it is recommended to add this directory to your path in order to execute CASS as described below.

## 14.2 Using CASS to Analyze Programs

CASS is intended to analyze various operational properties of Curry programs. Currently, it contains more than a dozen program analyses for various properties. Since most of these analyses are based on abstract interpretations, they usually approximate program properties. To see the list of all available analyses, use the help option of CASS:

```
> cass -h
Usage: ...
...
Registered analyses names:
...
Demand: Demanded arguments
Deterministic: Deterministic operations
...
```

More information about the meaning of the various analyses can be obtained by adding the short name of the analysis:

```
> cass -h Deterministic
...
```

For instance, consider the following Curry module `Rev.curry`:
append :: [a] → [a] → [a]
append [] ys = ys
append (x:xs) ys = x : append xs ys

rev :: [a] → [a]
rev [] = []
rev (x:xs) = append (rev xs) [x]

main :: Int → Int → [Int]
main x y = rev [x .. y]

CASS supports three different usage modes to analyze this program.

14.2.1 Batch Mode

In the batch mode, CASS is started as a separate application via the shell command cass, where the analysis name and the name of the module to be analyzed must be provided:

> cass Demand Rev
append : demanded arguments: 1
main : demanded arguments: 1,2
rev : demanded arguments: 1

The Demand analysis shows the list of argument positions (e.g., 1 for the first argument) which are demanded in order to reduce an application of the operation to some constructor-rooted value. Here we can see that both arguments of main are demanded whereas only the first argument of append is demanded. This information could be used in a Curry compiler to produce more efficient target code.

The batch mode is useful to test a new analysis and get the information in human-readable form so that one can experiment with different abstractions or analysis methods.

14.2.2 API Mode

The API mode is intended to use analysis information in some application implemented in Curry. Since CASS is implemented in Curry, one can import the modules of the CASS implementation and use the CASS interface operations to start an analysis and use the computed results. For instance, CASS provides an operation (defined in the module AnalysisServer)

analyzeGeneric :: Analysis a → String → IO (Either (ProgInfo a) String)
to apply an analysis (first argument) to some module (whose name is given in the second argument). The result is either the analysis information computed for this module or an error message in case of some execution error.

The modules of the CASS implementation are stored in the directory kics2home/currytools/CASS and the modules implementing the various program analyses are stored in kics2home/currytools/analysis. Hence, one should add these directories to the Curry load path when using CASS in API mode.

9More output is generated when the parameter debugLevel is changed in the configuration file .curryanalysisrc which is installed in the user’s home directory when CASS is started for the first time.
The CASS module \texttt{GenericProgInfo} contains operations to access the analysis information computed by CASS. For instance, the operation

\[
\text{lookupProgInfo} :: \text{QName} \rightarrow \text{ProgInfo} \ a \rightarrow \text{Maybe} \ a
\]

returns the information about a given qualified name in the analysis information, if it exists. As a simple example, consider the demand analysis which is implemented in the module \texttt{Demandedness} by the following operation:

\[
\text{demandAnalysis} :: \text{Analysis} \ \text{DemendedArgs}
\]

\texttt{DemendedArgs} is just a type synonym for \texttt{[Int]}. We can use this analysis in the following simple program:

\begin{verbatim}
import AnalysisServer (analyzeGeneric)
import GenericProgInfo (lookupProgInfo)
import Demandedness (demandAnalysis)

demandedArgumentsOf :: String → String → IO [Int]
demandedArgumentsOf modname fname = do
deminfo <- analyzeGeneric demandAnalysis modname >>= return . either id error
return $ maybe [] id (lookupProgInfo (modname, fname) deminfo)
\end{verbatim}

Of course, in a realistic program, the program analysis is performed only once and the computed information \texttt{deminfo} is passed around to access it several times. Nevertheless, we can use this simple program to compute the demanded arguments of \texttt{Rev.main}:

\begin{verbatim}
...> demandedArgumentsOf "Rev" "main"
[1,2]
\end{verbatim}

\subsection*{14.2.3 Server Mode}

The server mode of CASS can be used in an application implemented in some language that does not have a direct interface to Curry. In this case, one can connect to CASS via some socket using a simple communication protocol that is specified in the file \texttt{kics2home/currytools/CASS/Protocol.txt} and sketched below.

To start CASS in the server mode, one has to execute the command

\begin{verbatim}
> cass --server [ -p <port> ]
\end{verbatim}

where an optional port number for the communication can be provided. Otherwise, a free port number is chosen and shown. In the server mode, CASS understands the following commands:

\begin{verbatim}
GetAnalysis
SetCurryPath <dir1>:\<dir2>:\...
AnalyzeModule <analysis name> <output type> <module name>
AnalyzeInterface <analysis name> <output type> <module name>
AnalyzeFunction <analysis name> <output type> <module name> <function name>
AnalyzeDataConstructor <analysis name> <output type> <module name> <constructor name>
AnalyzeTypeConstructor <analysis name> <output type> <module name> <type name>
StopServer
\end{verbatim}
The output type can be **Text**, **CurryTerm**, or **XML**. The answer to each request can have two formats:

```
error <error message>
```

if an execution error occurred, or

```
ok <n>
<result text>
```

where `<n>` is the number of lines of the result text. For instance, the answer to the command **GetAnalysis** is a list of all available analyses. The list has the form

```
<analysis name> <output type>
```

For instance, a communication could be:

```
> GetAnalysis
< ok 5
< Deterministic CurryTerm
< Deterministic Text
< Deterministic XML
< HigherOrder CurryTerm
< DependsOn CurryTerm
```

The command **SetCurryPath** instructs CASS to use the given directories to search for modules to be analyzed. This is necessary since the CASS server might be started in a different location than its client.

Complete modules are analyzed by **AnalyzeModule**, whereas **AnalyzeInterface** returns only the analysis information of exported entities. Furthermore, the analysis results of individual functions, data or type constructors are returned with the remaining analysis commands. Finally, **StopServer** terminates the CASS server.

For instance, if we start CASS by

```
> cass --server -p 12345
```

we can communicate with CASS as follows (user inputs are prefixed by “>”):

```
> telnet localhost 12345
Connected to localhost.
> GetAnalysis
ok 57
Overlapping XML
Overlapping CurryTerm
Overlapping Text
Deterministic XML
...
> AnalyzeModule Demand Text Rev
ok 3
append : demanded arguments: 1
main : demanded arguments: 1,2
rev : demanded arguments: 1
> AnalyzeModule Demand CurryTerm Rev
ok 1
```
14.3 Implementing Program Analyses

Each program analysis accessible by CASS must be registered in the CASS module Registry. The registered analysis must contain an operation of type

```
Analysis a
```

where \(a\) denotes the type of analysis results. For instance, the Overlapping analysis is implemented as a function

```
overlapAnalysis :: Analysis Bool
```

where the Boolean analysis result indicates whether a Curry operation is defined by overlapping rules.

In order to add a new analysis to CASS, one has to implement a corresponding analysis operation, registering it in the module Registry (in the constant registeredAnalysis) and compile the modified CASS implementation.

An analysis is implemented as a mapping from Curry programs represented in FlatCurry into the analysis result. Hence, to implement the Overlapping analysis, we define the following operation on function declarations in FlatCurry format:

```
import FlatCurry.Types
...

isOverlappingFunction :: FuncDecl \rightarrow \text{Bool}
```
isOverlappingFunction (Func _ _ _ (Rule _ e)) = orInExpr e
isOverlappingFunction (Func f _ _ (External _)) = f==("Prelude","?")

-- Check an expression for occurrences of Or:

orInExpr :: Expr → Bool
orInExpr (Var _) = False
orInExpr (Lit _) = False
orInExpr (Comb _ f es) = f==(pre "?" || any orInExpr es
orInExpr (Free _ e) = orInExpr e
orInExpr (Let bs e) = any orInExpr (map snd bs) || orInExpr e
orInExpr (Or _ _) = True
orInExpr (Case _ e bs) = orInExpr e || any orInBranch bs
    where orInBranch (Branch _ be) = orInExpr be
orInExpr (Typed e _) = orInExpr e

In order to enable the inclusion of different analyses in CASS, CASS offers several constructor
operations for the abstract type “Analysis a” (defined in the CASS module Analysis). Each analysis
has a name provided as a first argument to these constructors. The name is used to store the analysis
information persistently and to pass specific analysis tasks to analysis workers. For instance, a simple
function analysis which depends only on a given function definition can be defined by the analysis
constructor

    simpleFuncAnalysis :: String → (FuncDecl → a) → Analysis a

The arguments are the analysis name and the actual analysis function. Hence, the “overlapping
rules” analysis can be specified as

    import Analysis
...

    overlapAnalysis :: Analysis Bool
    overlapAnalysis = simpleFuncAnalysis "Overlapping" isOverlappingFunction

Another analysis constructor supports the definition of a function analysis with dependencies (which
is implemented via a fixpoint computation):

    dependencyFuncAnalysis :: String → a → (FuncDecl → [(QName,a)] → a)
                          → Analysis a

Here, the second argument specifies the start value of the fixpoint analysis, i.e., the bottom element
of the abstract domain.

For instance, a determinism analysis could be based on an abstract domain described by the data type

    data Deterministic = NDet | Det

Here, Det is interpreted as “the operation always evaluates in a deterministic manner on ground
constructor terms.” However, NDet is interpreted as “the operation might evaluate in different ways
for given ground constructor terms.” The apparent imprecision is due to the approximation of the
analysis. For instance, if the function \( f \) is defined by overlapping rules and the function \( g \) might
call \( f \), then \( g \) is judged as non-deterministic (since it is generally undecidable whether \( f \) is actually
called by \( g \) in some run of the program).
The determinism analysis requires to examine the current function as well as all directly or indirectly called functions for overlapping rules. Due to recursive function definitions, this analysis cannot be done in one shot—it requires a fixpoint computation. CASS provides such fixpoint computations and requires only the implementation of an operation of type

\[ \text{FuncDecl} \rightarrow \left[ (\text{QName}, \text{a}) \right] \rightarrow \text{a} \]

where “a” denotes the type of abstract values. The second argument of type \( \left[ (\text{QName}, \text{a}) \right] \) represents the currently known analysis values for the functions directly used in this function declaration.

In our example, the determinism analysis can be implemented by the following operation:

```haskell
detFunc :: FuncDecl \rightarrow \left[ (\text{QName}, \text{Deterministic}) \right] \rightarrow \text{Deterministic}
detFunc (Func f _ _ _ (Rule _ e)) calledFuncs =
  if orInExpr e || freeVarInExpr e || any (==NDet) (map snd calledFuncs)
  then NDet
  else Det
```

Thus, it computes the abstract value \( \text{NDet} \) if the function itself is defined by overlapping rules or contains free variables that might cause non-deterministic guessing (we omit the definition of \( \text{freeVarInExpr} \) since it is quite similar to \( \text{orInExpr} \)), or if it depends on some non-deterministic function.

The complete determinism analysis can be specified as

```haskell
detAnalysis :: Analysis Deterministic
detAnalysis = dependencyFuncAnalysis "Deterministic" Det detFunc
```

This definition is sufficient to execute the analysis with CASS since the analysis system takes care of computing fixpoints, calling the analysis functions with appropriate values, analyzing imported modules, etc. Nevertheless, the analysis must be defined so that the fixpoint computation always terminates. This can be achieved by using an abstract domain with finitely many values and ensuring that the analysis function is monotone w.r.t. some ordering on the values.
15 ERD2Curry: A Tool to Generate Programs from ER Specifications

ERD2Curry is a tool to generate Curry code to access and manipulate data persistently stored in relational databases. The Curry code is generated from a description of the logical model of the database in form of an entity relationship diagram. The idea of this tool is described in detail in [10]. Thus, we describe only the basic steps to use this tool.

15.1 Installation

The current implementation of ERD2Curry is a package managed by the Curry Package Manager CPM (see also Section 6). Thus, to install the newest version of ERD2Curry, use the following commands:

```bash
> cypm update
> cypm install ertools
```

This downloads the newest package, compiles it, and places the executable `erd2curry` into the directory `$HOME/.cpm/bin`. Hence it is recommended to add this directory to your path in order to execute ERD2Curry as described below.

15.2 Basic Usage

If one creates an entity relationship diagram (ERD) with the Umbrello UML Modeller, one has to store its XML description in XMI format (as offered by Umbrello) in a file, e.g., “myerd.xmi”. This description can be compiled into a Curry program by the command

```bash
erd2curry -x myerd.xmi
```

If `MyData` is the name of the ERD, the Curry program file “MyData_curry” is generated containing all the necessary database access code as described in [10]. In addition to the generated Curry program file, two auxiliary program files `ERDGeneric.curry` and `KeyDatabase.curry` are created in the same directory.

If one does not want to use the Umbrello UML Modeller, which might be the preferred method since the interface to the Umbrello UML Modeller is no longer actively supported, one can also define an ERD in a Curry program as a (exported!) top-level operation of type `ERD` (w.r.t. the type definition given in the library `kics2home/lib/Database/ERD.curry`). The directory `examples` in the package ertools contains two examples for such ERD program files:

- **BlogERD_curry**: This is a simple ERD model for a blog with entries, comments, and tags.
- **UniERD_curry**: This is an ERD model for university lectures as presented in the paper [10].

Figure 6 shows the ER specification stored in the Curry program file “BlogERD.curry”. This ER specification can be compiled into a Curry program by the command

```bash
erd2curry BlogERD_curry
```

---

10If you installed ERD2Curry as described above, the downloaded ertools package is located in the directory `$HOME/.cpm/bin_packages/ertools`. 

---
import Database.ERD

blogERD :: ERD
blogERD =
  ERD "Blog"
  [Entity "Entry"
    [Attribute "Title" (StringDom Nothing) Unique False,
     Attribute "Text" (StringDom Nothing) NoKey False,
     Attribute "Author" (StringDom Nothing) NoKey False,
     Attribute "Date" (DateDom Nothing) NoKey False],
    Entity "Comment"
    [Attribute "Text" (StringDom Nothing) NoKey False,
     Attribute "Author" (StringDom Nothing) NoKey False,
     Attribute "Date" (DateDom Nothing) NoKey False],
    Entity "Tag"
    [Attribute "Name" (StringDom Nothing) Unique False]
  ]
  [Relationship "Commenting"
    [REnd "Entry" "commentsOn" (Exactly 1),
     REnd "Comment" "isCommentedBy" (Between 0 Infinite)],
    Relationship "Tagging"
    [REnd "Entry" "tags" (Between 0 Infinite),
     REnd "Tag" "tagged" (Between 0 Infinite)]
  ]

Figure 6: The Curry program BlogERD.curry

There is also the possibility to visualize an ER specification as a graph with the graph visualization program dotty (for this purpose, it might be necessary to adapt the definition of dotviewcommand in your “.kics2rc” file, see Section 2.7, according to your local environment). The visualization can be performed by the command

erd2curry -v BlogERD.curry
16 Spicey: An ER-based Web Framework

Spicey is a framework to support the implementation of web-based systems in Curry. Spicey generates an initial implementation from an entity-relationship (ER) description of the underlying data. The generated implementation contains operations to create and manipulate entities of the data model, supports authentication, authorization, session handling, and the composition of individual operations to user processes. Furthermore, the implementation ensures the consistency of the database w.r.t. the data dependencies specified in the ER model, i.e., updates initiated by the user cannot lead to an inconsistent state of the database.

16.1 Installation

The actual implementation of Spicey is a package managed by the Curry Package Manager CPM (see also Section 6). Thus, to install the newest version of Spicey, use the following commands:

```bash
> cypm update
> cypm install spicey
```

This downloads the newest package, compiles it, and places the executable `spiceup` into the directory `$HOME/.cpm/bin`. Hence it is recommended to add this directory to your path in order to execute Spicey as described below.

16.2 Usage

The idea of this tool, which is part of the distribution of KiCS2, is described in detail in [22]. Thus, we summarize only the basic steps to use this tool in order to generate a web application.

First, one has to create a textual description of the entity-relationship model in a Curry program file as an (exported!) top-level operation type `ERD` (w.r.t. the type definitions given in the system library `Database.ERD`) and store it in some program file, e.g., “MyERD.curry”. The directory `examples` in the package `spicey` contains two examples for such ERD program files:

- **BlogERD.curry**: This is a simple ER model for a blog with entries, comments, and tags, as presented in the paper [22].
- **UniERD.curry**: This is an ER model for university lectures as presented in the paper [10].

Then change to the directory in which you want to create the project sources. Execute the command

```
spiceup .../MyERD.curry
```

with the path to the ERD program as a parameter. You can also provide a file name for the SQLite3 database used by the application generated by Spicey, e.g.,

```
spiceup --db MyData.db .../MyERD.curry
```

If the parameter “--db DBFILE” is not provided, then `DBFILE` is set to the default name “`ERD.db`” (where `ERD` is the name of the specified ER model). Since this specification will be used in the generated web programs, a relative database file name will be relative to the place where the web

---

11If you installed Spicey as described above, the downloaded `spicey` package is located in the directory `$HOME/.cpm/bin_packages/spicey`. 

programs are stored. In order to avoid such confusion, it might be better to specify an absolute path name for the database file.

After the generation of this project (see the generated file README.txt for information about the generated project structure), one can compile the generated programs by

```
make compile
```

In order to generate the executable web application, configure the generated Makefile by adapting the variable WEBSERVERDIR to the location where the compiled cgi programs should be stored, and run

```
make deploy
```

After the successful compilation and deployment of all files, the application is executable in a web browser by selecting the URL `<URL of web dir>/spicey.cgi`. 
17 curry-peval: A Partial Evaluator for Curry

peval is a tool for the partial evaluation of Curry programs. It operates on the FlatCurry representation and can thus easily be incorporated into the normal compilation chain. The essence of partial evaluation is to anticipate at compile time (or partial evaluation time) some of the computations normally performed at run time. Typically, partial evaluation is worthwhile for functions or operations where some of the input arguments are already known at compile time, or operations built by the composition of multiple other ones. The theoretical foundations, design and implementation of the partial evaluator is described in detail in [31].

17.1 Installation

The current implementation of the partial evaluator is a package managed by the Curry Package Manager CPM (see also Section 6). Thus, to install the newest version of the partial evaluator, use the following commands:

> cypm update
> cypm install peval

This downloads the newest package, compiles it, and places the executable curry-peval into the directory \$HOME/.cpm/bin. Hence it is recommended to add this directory to your path in order to use the partial evaluator as described below.

17.2 Basic Usage

The partial evaluator is supplied as a binary that can be invoked for a single or multiple modules that should be partially evaluated. In each module, the partially evaluator assumes the parts of the program that should be partially evaluated to be annotated by the function

```curry
PEVAL :: a
PEVAL x = x
```

predefined in the module Prelude, such that the user can choose the parts to be considered.

To give an example, we consider the following module which is assumed to be placed in the file Examples/power4.curry:

```curry
square x = x * x
even x = mod x 2 == 0
power n x = if n <= 0 then 1
                    else if (even n) then power (div n 2) (square x)
                    else x * (power (n - 1) x)

power4 x = PEVAL (power 4 x)
```

By the call to PEVAL, the expression power 4 x is marked for partial evaluation, such that the function power will be improved w.r.t. the arguments 4 and x. Since the first argument is known in this case, the partial evaluator is able to remove the case distinctions in the implementation of power, and we invoke it via

```
$ curry-peval Examples/power4.curry
Curry Partial Evaluator
```
Annotated Expressions
--------------------
power4.power 4 v1

Final Partial Evaluation
------------------------
power4._pe0 :: Prelude.Int → Prelude.Int
power4._pe0 v1 = let { v2 = v1 * v1 } in v2 * v2

Writing specialized program into file 'Examples/.curry/power4_pe.fcy'.

Note that the partial evaluator successfully removed the case distinction, such that the operation power4 can be expected to run reasonably faster. The new auxiliary function power4._pe0 is integrated into the existing module such that only the implementation of power4 is changed, which becomes visible if we increase the level of verbosity:

$ curry-peval -v2 Examples/power4.curry
Curry Partial Evaluator
Version 0.1 of 12/09/2016
CAU Kiel

Annotated Expressions
--------------------
power4.power 4 v1

Resulting program
-----------------
module power4 ( power4.square, power4.even, power4.power, power4.power4 ) where

import Prelude

power4.square :: Prelude.Int → Prelude.Int
power4.square v1 = v1 * v1

power4.even :: Prelude.Int → Prelude.Bool
power4.even v1 = (Prelude.mod v1 2) == 0

power4.power :: Prelude.Int → Prelude.Int → Prelude.Int
power4.power v1 v2 = case (v1 <= 0) of
  Prelude.True → 1
  Prelude.False → case (power4.even v1) of
    Prelude.True → power4.power (Prelude.div v1 2) (power4.square v2)
    Prelude.False → v2 * (power4.power (v1 - 1) v2)

power4.power4 :: Prelude.Int → Prelude.Int
power4.power4 v1 = power4._pe0 v1

power4._pe0 :: Prelude.Int → Prelude.Int
power4._pe0 v1 = let { v2 = v1 * v1 } in v2 * v2

17.3 Options

The partial evaluator can be parametrized using a number of options, which can also be shown using --help.

-h, -?, --help These options trigger the output of usage information.

-V, --version These options trigger the output of the version information of the partial evaluator.

-d, --debug This flag is intended for development and testing issues only, and necessary to print the resulting program to the standard output stream even if the verbosity is set to zero.

--assert, --closed These flags enable some internal assertions which are reasonable during development of the partial evaluator.

--no-funpats Normally, functions defined using functional patterns are automatically considered for partial evaluation, since their annotation using PEVAL is a little bit cumbersome. However, this automatic consideration can be disabled using this flag.

-v n, --verbosity=n Set the verbosity level to n, see above for the explanation of the different levels.

--color=mode, --colour=mode Set the coloring mode to mode, see above for the explanation of the different modes.

-S semantics, --semantics=semantics Allows the use to choose a semantics used during partial evaluation. Note that only the natural semantics can be considered correct for non-confluent programs, which is why it is the default semantics [31]. However, the rInt calculus can also be chosen which is based on term rewriting, thus implementing a run-time choice semantics [1]. The letrw semantics is currently not fully supported, but implements the gist of let-rewriting [29].

--abstract=mode During partial evaluation, all expressions that may potentially occur in the evaluation of an annotated expression are considered and evaluated, in order to ensure that all these expressions are also defined in the resulting program. Unfortunately, this imposes the risk of non-termination, which is why similar expressions are generalized according to the abstraction criterion. While the none criterion avoids generalizations and thus may lead to non-termination of the partial evaluator, the criteria wqo and wfo both ensure termination. In general, the criterion wqo seems to be a good compromise of ensured termination and the quality of the computed result program.

-P mode, --proceed=mode While the abstraction mode is responsible to limit the number of different expressions to be considered, the proceed mode limits the number of function calls to be
evaluated during the evaluation of a single expressions. While the mode one only allows a single function call to be evaluated, the mode each allows a single call of each single function, while all puts no restrictions on the number of function calls to be evaluated. Clearly, the last alternative also imposes a risk of non-termination.

--suffix=SUFFIX Set the suffix appended to the file name to compute the output file. If the suffix is set to the empty string, then the original FlatCurry file will be replaced.
18 Technical Problems

One can implement distributed systems with KiCS2 by the use of the library NamedSocket (Section A.2.25) that supports a socket communication with symbolic names rather than natural numbers. For instance, this library is the basis of programming dynamic web pages with the library HTML (Section ??). However, it might be possible that some technical problems arise due to the use of named sockets. Therefore, this section gives some information about the technical requirements of KiCS2 and how to solve problems due to these requirements.

There is one fixed port that is used by the implementation of KiCS2:

**Port 8767:** This port is used by the Curry Port Name Server (CPNS) to implement symbolic names for named sockets in Curry. If some other process uses this port on the machine, the distribution facilities defined in the module NamedSocket cannot be used.

If these features do not work, you can try to find out whether this port is in use by the shell command “netstat -a | fgrep 8767” (or similar).

The CPNS is implemented as a demon listening on its port 8767 in order to serve requests about registering a new symbolic name for a named socket or asking the physical port number of an registered named socket. The demon will be automatically started for the first time on a machine when a user runs a program using named sockets. It can also be manually started and terminated by the scripts kics2home/currytools/cpns/start and kics2home/currytools/cpns/stop. If the demon is already running, the command kics2home/currytools/cpns/start does nothing (so it can be always executed before invoking a Curry program using named sockets).

If you detect any further technical problem, please write to

kics2@curry-language.org

A Libraries of the KiCS2 Distribution

The KiCS2 distribution comes with an extensive collection of libraries for application programming. The libraries for meta-programming by representing Curry programs as datatypes in Curry are described in the following subsection in more detail. The complete set of libraries with all exported types and functions are described in the further subsections. For a more detailed online documentation of all libraries of KiCS2, see http://www-ps.informatik.uni-kiel.de/kics2/lib/index.html.

A.1 AbstractCurry and FlatCurry: Meta-Programming in Curry

To support meta-programming, i.e., the manipulation of Curry programs in Curry, there are system modules FlatCurry.Types (Section ??) and AbstractCurry.Types (Section ??) which define datatypes for the representation of Curry programs. AbstractCurry.Types is a more direct representation of a Curry program, whereas FlatCurry.Types is a simplified representation where local function definitions are replaced by global definitions (i.e., lambda lifting has been performed) and pattern matching is translated into explicit case/or expressions. Thus, FlatCurry.Types can be used for more back-end oriented program manipulations (or, for writing new back ends for Curry), whereas AbstractCurry.Types is intended for manipulations of programs that are more oriented towards the source program.

There are predefined I/O actions to read AbstractCurry and FlatCurry programs: AbstractCurry.Files.readCurry and FlatCurry.Files.readFlatCurry). These actions parse the corresponding source program and return a data term representing this program (according to the definitions in the modules AbstractCurry.Types and FlatCurry.Types).

Since all datatypes are explained in detail in these modules, we refer to the online documentation of these modules.

As an example, consider a program file “test.curry” containing the following two lines:

\[
\begin{align*}
\text{rev[]} & = [] \\
\text{rev}(x:xs) & = (\text{rev} \hspace{1em} xs) ++ [x]
\end{align*}
\]

Then the I/O action (FlatCurry.Files.readFlatCurry "test") returns the following term:

\[
\text{(Prog "test" \\
["Prelude"] \\
[Func ("test","rev") 1 Public} \\
\text{[FuncType (TCons ("Prelude","[]") [(TVar 0)]) \\
\hspace{1em} (TCons ("Prelude","[]") [(TVar 0)])]) \\
\text{(Rule [0} \\
\hspace{1em} (Case Flex (Var 1) \\
\hspace{2em} [Branch (Pattern ("Prelude","[]") []) \\
\hspace{3em} (Comb ConsCall ("Prelude","[]") []), \\
\hspace{3em} Branch (Pattern ("Prelude",:"") [2,3]) \\
\hspace{4em} (Comb FuncCall ("Prelude","++") \\
\hspace{5em} [Comb FuncCall ("test","rev") [Var 3],}
\]

\[\text{http://www-ps.informatik.uni-kiel.de/kics2/lib/FlatCurry.Types.html and http://www-ps.informatik.uni-kiel.de/kics2/lib/AbstractCurry.Types.html}\]
A.2 General Libraries

A.2.1 Library AllSolutions

This module contains a collection of functions for obtaining lists of solutions to constraints. These operations are useful to encapsulate non-deterministic operations between I/O actions in order to connect the worlds of logic and functional programming and to avoid non-determinism failures on the I/O level.

In contrast the "old" concept of encapsulated search (which could be applied to any subexpression in a computation), the operations to encapsulate search in this module are I/O actions in order to avoid some anomalies in the old concept.

Exported functions:

getAllValues :: a → IO [a]

Gets all values of an expression (currently, via an incomplete depth-first strategy). Conceptually, all values are computed on a copy of the expression, i.e., the evaluation of the expression does not share any results. Moreover, the evaluation suspends as long as the expression contains unbound variables.

getOneValue :: a → IO (Maybe a)

Gets one value of an expression (currently, via an incomplete left-to-right strategy). Returns Nothing if the search space is finitely failed.

getAllSolutions :: (a → Bool) → IO [a]

Gets all solutions to a constraint (currently, via an incomplete depth-first left-to-right strategy). Conceptually, all solutions are computed on a copy of the constraint, i.e., the evaluation of the constraint does not share any results. Moreover, this evaluation suspends if the constraints contain unbound variables. Similar to Prolog’s findall.

getOneSolution :: (a → Bool) → IO (Maybe a)

Gets one solution to a constraint (currently, via an incomplete left-to-right strategy). Returns Nothing if the search space is finitely failed.

getAllFailures :: a → (a → Bool) → IO [a]

Returns a list of values that do not satisfy a given constraint.
A.2.2 Library Assertion

This module defines the datatype and operations for the Curry module tester "currytest".

Exported types:

data Assertion

    Datatype for defining test cases.

Exported constructors:

data ProtocolMsg

    The messages sent to the test GUI. Used by the currytest tool.

Exported constructors:

• TestModule :: String \t\rightarrow \quad\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\quad\rightarrow\quad\q
(assertEqualIO s a1 a2) asserts (with name s) that I/O actions a1 and a2 yield equal (w.r.t. ==) results.

seqStrActions :: IO (String,Bool) → IO (String,Bool) → IO (String,Bool)

Combines two actions and combines their results. Used by the currytest tool.

checkAssertion :: String → ((String,Bool) → IO (String,Bool)) → Assertion a → IO (String,Bool)

Executes and checks an assertion, and process the result by an I/O action. Used by the currytest tool.

writeAssertResult :: (String,Bool) → IO Int

Prints the results of assertion checking. If failures occurred, the return code is positive. Used by the currytest tool.

showTestMod :: Int → String → IO ()

Sends message to GUI for showing test of a module. Used by the currytest tool.

showTestCase :: Int → (String,Bool) → IO (String,Bool)

Sends message to GUI for showing result of executing a test case. Used by the currytest tool.

showTestEnd :: Int → IO ()

Sends message to GUI for showing end of module test. Used by the currytest tool.

showTestCompileError :: Int → IO ()

Sends message to GUI for showing compilation errors in a module test. Used by the currytest tool.

A.2.3 Library Char

Library with some useful functions on characters.

Exported functions:

isAscii :: Char → Bool

Returns true if the argument is an ASCII character.

isLatin1 :: Char → Bool

Returns true if the argument is an Latin-1 character.

isAsciiLower :: Char → Bool

Returns true if the argument is an ASCII lowercase letter.
isAsciiUpper :: Char → Bool
   Returns true if the argument is an ASCII uppercase letter.

isControl :: Char → Bool
   Returns true if the argument is a control character.

isUpper :: Char → Bool
   Returns true if the argument is an uppercase letter.

isLower :: Char → Bool
   Returns true if the argument is a lowercase letter.

isAlpha :: Char → Bool
   Returns true if the argument is a letter.

isDigit :: Char → Bool
   Returns true if the argument is a decimal digit.

isAlphaNum :: Char → Bool
   Returns true if the argument is a letter or digit.

isBinDigit :: Char → Bool
   Returns true if the argument is a binary digit.

isOctDigit :: Char → Bool
   Returns true if the argument is an octal digit.

isHexDigit :: Char → Bool
   Returns true if the argument is a hexadecimal digit.

isSpace :: Char → Bool
   Returns true if the argument is a white space.

toUpper :: Char → Char
   Converts lowercase into uppercase letters.

toLower :: Char → Char
   Converts uppercase into lowercase letters.

digitToInt :: Char → Int
   Converts a (hexadecimal) digit character into an integer.

intToDigit :: Int → Char
   Converts an integer into a (hexadecimal) digit character.
A.2.4 Library Combinatorial

A collection of common non-deterministic and/or combinatorial operations. Many operations are intended to operate on sets. The representation of these sets is not hidden; rather sets are represented as lists. Ideally these lists contains no duplicate elements and the order of their elements cannot be observed. In practice, these conditions are not enforced.

Exported functions:

permute :: [a] → [a]

Compute any permutation of a list.

subset :: [a] → [a]

Compute any sublist of a list. The sublist contains some of the elements of the list in the same order.

allSubsets :: [a] → [[a]]

Compute all the sublists of a list.

splitSet :: [a] → ([a], [a])

Split a list into any two sublists.

sizedSubset :: Int → [a] → [a]

Compute any sublist of fixed length of a list. Similar to subset, but the length of the result is fixed.

partition :: [a] → [[a]]

Compute any partition of a list. The output is a list of non-empty lists such that their concatenation is a permutation of the input list. No guarantee is made on the order of the arguments in the output.

A.2.5 Library CPNS

Implementation of a Curry Port Name Server based on raw sockets. It is used to implement the library Ports for distributed programming with ports.

Exported functions:

cpnsStart :: IO ()

Starts the "Curry Port Name Server" (CPNS) running on the local machine. The CPNS is responsible to resolve symbolic names for ports into physical socket numbers so that a port can be reached under its symbolic name from any machine in the world.

cpnsShow :: IO ()
Shows all registered ports at the local CPNS demon (in its logfile).

```haskell
cponsStop :: IO ()
```
Terminates the local CPNS demon

```haskell
registerPort :: String → Int → Int → IO ()
```
Registers a symbolic port at the local host.

```haskell
getPortInfo :: String → String → IO (Int,Int)
```
Gets the information about a symbolic port at some host.

```haskell
unregisterPort :: String → IO ()
```
Unregisters a symbolic port at the local host.

```haskell
cponsAlive :: Int → String → IO Bool
```
Tests whether the CPNS demon at a host is alive.

```haskell
main :: IO ()
```
Main function for CPNS demon. Check arguments and execute command.

### A.2.6 Library CSV

Library for reading/writing files in CSV format. Files in CSV (comma separated values) format can be imported and exported by most spreadsheet and database applications.

**Exported functions:**

```haskell
writeCSVFile :: String → [[String]] → IO ()
```
Writes a list of records (where each record is a list of strings) into a file in CSV format.

```haskell
showCSV :: [[String]] → String
```
Shows a list of records (where each record is a list of strings) as a string in CSV format.

```haskell
readCSVFile :: String → IO [[String]]
```
Reads a file in CSV format and returns the list of records (where each record is a list of strings).

```haskell
readCSVFileWithDelims :: String → String → IO [[String]]
```
Reads a file in CSV format and returns the list of records (where each record is a list of strings).

```haskell
readCSV :: String → [[String]]
```
Reads a string in CSV format and returns the list of records (where each record is a list of strings).

```haskell
readCSVWithDelims :: String → String → [[String]]
```
Reads a string in CSV format and returns the list of records (where each record is a list of strings).
A.2.7 Library Debug

This library contains some useful operations for debugging programs.

Exported functions:

\texttt{trace :: String → a → a}

Prints the first argument as a side effect and behaves as identity on the second argument.

\texttt{traceId :: String → String}

Prints the first argument as a side effect and returns it afterwards.

\texttt{traceShow :: a → b → b}

Prints the first argument using \texttt{show} and returns the second argument afterwards.

\texttt{traceShowId :: a → a}

Prints the first argument using \texttt{show} and returns it afterwards.

\texttt{traceIO :: String → IO ()}

Output a trace message from the \texttt{IO} monad.

\texttt{assert :: Bool → String → a → a}

Assert a condition w.r.t. an error message. If the condition is not met it fails with the given error message, otherwise the third argument is returned.

\texttt{assertIO :: Bool → String → IO ()}

Assert a condition w.r.t. an error message from the \texttt{IO} monad. If the condition is not met it fails with the given error message.

A.2.8 Library Directory

Library for accessing the directory structure of the underlying operating system.

Exported functions:

\texttt{doesFileExist :: String → IO Bool}

Returns true if the argument is the name of an existing file.

\texttt{doesDirectoryExist :: String → IO Bool}

Returns true if the argument is the name of an existing directory.

\texttt{fileSize :: String → IO Int}

Returns the size of the file.
getModificationTime :: String → IO ClockTime

    Returns the modification time of the file.

gGetCurrentDirectory :: IO String

    Returns the current working directory.

gsetCurrentDirectory :: String → IO ()

    Sets the current working directory.

ggetDirectoryContents :: String → IO [String]

    Returns the list of all entries in a directory.

gcreateDirectory :: String → IO ()

    Creates a new directory with the given name.

gcreateDirectoryIfMissing :: Bool → String → IO ()

    Creates a new directory with the given name if it does not already exist. If the first
    parameter is True it will also create all missing parent directories.

gremoveDirectory :: String → IO ()

    Deletes a directory from the file system.

grenameDirectory :: String → String → IO ()

    Renames a directory.

ggetHomeDirectory :: IO String

    Returns the home directory of the current user.

ggetTemporaryDirectory :: IO String

    Returns the temporary directory of the operating system.

ggetAbsolutePath :: String → IO String

    Convert a path name into an absolute one. For instance, a leading ~ is replaced by the
    current home directory.

gremoveFile :: String → IO ()

    Deletes a file from the file system.

grenameFile :: String → String → IO ()

    Renames a file.

gcopyFile :: String → String → IO ()

    Copy the contents from one file to another file
A.2.9 Library Distribution

This module contains functions to obtain information concerning the current distribution of the Curry implementation, e.g., compiler version, load paths, front end.

Exported types:

```haskell
data FrontendTarget

data FrontendTarget
    -- Data type for representing the different target files that can be produced by the front end of the Curry compiler.

    -- Exported constructors:
    • FCY :: FrontendTarget
        FCY
        -- FlatCurry file ending with .fcy
    • FINT :: FrontendTarget
        FINT
        -- FlatCurry interface file ending with .fint
    • ACY :: FrontendTarget
        ACY
        -- AbstractCurry file ending with .acy
    • UACY :: FrontendTarget
        UACY
        -- Untyped (without type checking) AbstractCurry file ending with .uacy
    • HTML :: FrontendTarget
        HTML
        -- colored HTML representation of source program
    • CY :: FrontendTarget
        CY
        -- source representation employed by the frontend
    • TOKS :: FrontendTarget
        TOKS
        -- token stream of source program
```

93
data FrontendParams

Abstract data type for representing parameters supported by the front end of the Curry compiler.

Exported constructors:

Exported functions:
curryCompiler :: String

The name of the Curry compiler (e.g., "pakcs" or "kics2").
curryCompilerMajorVersion :: Int

The major version number of the Curry compiler.
curryCompilerMinorVersion :: Int

The minor version number of the Curry compiler.
curryRuntime :: String

The name of the run-time environment (e.g., "sicstus", "swi", or "ghc")
curryRuntimeMajorVersion :: Int

The major version number of the Curry run-time environment.
curryRuntimeMinorVersion :: Int

The minor version number of the Curry run-time environment.
installDir :: String

Path of the main installation directory of the Curry compiler.
rcFileName :: IO String

The name of the file specifying configuration parameters of the current distribution. This file must have the usual format of property files (see description in module PropertyFile).
rcFileContents :: IO [(String,String)]

Returns the current configuration parameters of the distribution. This action yields the list of pairs (var,val).
getRcVar :: String → IO (Maybe String)

Look up a specific configuration variable as specified by user in his rc file. Uppercase/lowercase is ignored for the variable names.
getRcVars :: [String] → IO [Maybe String]
Look up configuration variables as specified by user in his rc file. Uppercase/lowercase is ignored for the variable names.

\texttt{splitModuleFileName :: String → String → (String,String)}

Split the \texttt{FilePath} of a module into the directory prefix and the \texttt{FilePath} corresponding to the module name. For instance, the call \texttt{splitModuleFileName "Data.Set" "lib/Data/Set.curry" evaluates to ("lib", "Data/Set.curry"). This can be useful to compute output directories while retaining the hierarchical module structure.

\texttt{splitModuleIdentifiers :: String → [String]}

Split up the components of a module identifier. For instance, \texttt{splitModuleIdentifiers "Data.Set" evaluates to ["Data", "Set"].

\texttt{joinModuleIdentifiers :: [String] → String}

Join the components of a module identifier. For instance, \texttt{joinModuleIdentifiers ["Data", "Set"] evaluates to "Data.Set".}

\texttt{stripCurrySuffix :: String → String}

Strips the suffix ".curry" or ".lcurry" from a file name.

\texttt{modNameToPath :: String → String}

Transforms a hierarchical module name into a path name, i.e., replace the dots in the name by directory separator chars.

\texttt{currySubdir :: String}

Name of the sub directory where auxiliary files (.fint, .fcy, etc) are stored.

\texttt{inCurrySubdir :: String → String}

Transforms a path to a module name into a file name by adding the \texttt{currySubDir} to the path and transforming a hierarchical module name into a path. For instance, \texttt{inCurrySubdir "mylib/Data.Char" evaluates to "mylib/.curry/Data/Char".}

\texttt{inCurrySubdirModule :: String → String → String}

Transforms a file name by adding the \texttt{currySubDir} to the file name. This version respects hierarchical module names.

\texttt{addCurrySubdir :: String → String}

Transforms a directory name into the name of the corresponding sub directory containing auxiliary files.

\texttt{sysLibPath :: [String]}

finding files in correspondence to compiler load path Returns the current path (list of directory names) of the system libraries.
getLoadPathForModule :: String → IO [String]

Returns the current path (list of directory names) that is used for loading modules w.r.t.
a given module path. The directory prefix of the module path (or "." if there is no such
prefix) is the first element of the load path and the remaining elements are determined
by the environment variable CURRYRPATH and the entry "libraries" of the system’s
rc file.

lookupModuleSourceInLoadPath :: String → IO (Maybe (String,String))

Returns a directory name and the actual source file name for a module by looking up
the module source in the current load path. If the module is hierarchical, the directory
is the top directory of the hierarchy. Returns Nothing if there is no corresponding source
file.

lookupModuleSource :: [String] → String → IO (Maybe (String,String))

Returns a directory name and the actual source file name for a module by looking up
the module source in the load path provided as the first argument. If the module is
hierarchical, the directory is the top directory of the hierarchy. Returns Nothing if there
is no corresponding source file.

defaultParams :: FrontendParams

The default parameters of the front end.

rcParams :: IO FrontendParams

The default parameters of the front end as configured by the compiler specific resource
configuration file.

setQuiet :: Bool → FrontendParams → FrontendParams

Set quiet mode of the front end.

setExtended :: Bool → FrontendParams → FrontendParams

Set extended mode of the front end.

setOverlapWarn :: Bool → FrontendParams → FrontendParams

Set overlap warn mode of the front end.

setFullPath :: [String] → FrontendParams → FrontendParams

Set the full path of the front end. If this parameter is set, the front end searches all
modules in this path (instead of using the default path).

setHtmlDir :: String → FrontendParams → FrontendParams

Set the htmldir parameter of the front end. Relevant for HTML generation.

setLogfile :: String → FrontendParams → FrontendParams
Set the logfile parameter of the front end. If this parameter is set, all messages produced by the front end are stored in this file.

**setSpecials :: String → FrontendParams → FrontendParams**

Set additional specials parameters of the front end. These parameters are specific for the current front end and should be used with care, since their form might change in the future.

**addTarget :: FrontendTarget → FrontendParams → FrontendParams**

Add an additional front end target.

**quiet :: FrontendParams → Bool**

Returns the value of the "quiet" parameter.

**extended :: FrontendParams → Bool**

Returns the value of the "extended" parameter.

**overlapWarn :: FrontendParams → Bool**

Returns the value of the "overlapWarn" parameter.

**fullPath :: FrontendParams → Maybe [String]**

Returns the full path parameter of the front end.

**htmldir :: FrontendParams → Maybe String**

Returns the htmldir parameter of the front end.

**logfile :: FrontendParams → Maybe String**

Returns the logfile parameter of the front end.

**specials :: FrontendParams → String**

Returns the special parameters of the front end.

**callFrontend :: FrontendTarget → String → IO ()**

In order to make sure that compiler generated files (like .fcy, .fint, .acy) are up to date, one can call the front end of the Curry compiler with this action. If the front end returns with an error, an exception is raised.

**callFrontendWithParams :: FrontendTarget → FrontendParams → String → IO ()**

In order to make sure that compiler generated files (like .fcy, .fint, .acy) are up to date, one can call the front end of the Curry compiler with this action where various parameters can be set. If the front end returns with an error, an exception is raised.
A.2.10 Library Either

Library with some useful operations for the Either data type.

Exported functions:

lefts :: [Either a b] → [a]

Extracts from a list of Either all the Left elements in order.

rights :: [Either a b] → [b]

Extracts from a list of Either all the Right elements in order.

isLeft :: Either a b → Bool

Return True if the given value is a Left-value, False otherwise.

isRight :: Either a b → Bool

Return True if the given value is a Right-value, False otherwise.

fromLeft :: Either a b → a

Extract the value from a Left constructor.

fromRight :: Either a b → b

Extract the value from a Right constructor.

partitionEithers :: [Either a b] → ([a],[b])

Partitions a list of Either into two lists. All the Left elements are extracted, in order, to the first component of the output. Similarly the Right elements are extracted to the second component of the output.

A.2.11 Library ErrorState

A combination of Error and state monad like ErrorT State in Haskell.

Exported types:

type ES a b c = b → Either a (c,b)

Error state monad.
Exported functions:

evalES :: (a → Either b (c,a)) → a → Either b c

Evaluate an ES monad

returnES :: a → b → Either c (a,b)

Lift a value into the ES monad

failES :: a → b → Either a (c,b)

Failing computation in the ES monad

(>+=) :: (a → Either b (c,a)) → (c → a → Either b (d,a)) → a → Either b (d,a)

Bind of the ES monad

(>++) :: (a → Either b (c,a)) → (a → Either b (d,a)) → a → Either b (d,a)

Sequence operator of the ES monad

(<$>) :: (a → b) → (c → Either d (a,c)) → c → Either d (b,c)

Apply a pure function onto a monadic value.

(<*>+) :: (a → Either b (c → d,a)) → (a → Either b (c,a)) → a → Either b (d,a)

Apply a function yielded by a monadic action to a monadic value.

gets :: a → Either b (a,a)

Retrieve the current state

puts :: a → a → Either b ((,),a)

Replace the current state

modify :: (a → a) → a → Either b ((,),a)

Modify the current state

mapES :: (a → b → Either c (d,b)) → [a] → b → Either c ([d],b)

Map a monadic function on all elements of a list by sequencing the effects.

concatMapES :: (a → b → Either c ([d],b)) → [a] → b → Either c ([d],b)

Same as concatMap, but for a monadic function.

mapAccumES :: (a → b → c → Either d ((a,e),(e,c))) → a → [b] → c → Either d ((a,[(e)],c),c)

Same as mapES but with an additional accumulator threaded through.
A.2.12 Library FileGoodies

A collection of useful operations when dealing with files.

Exported functions:

separatorChar :: Char

The character for separating hierarchies in file names. On UNIX systems the value is /. pathSeparatorChar :: Char

The character for separating names in path expressions. On UNIX systems the value is :.

suffixSeparatorChar :: Char

The character for separating suffixes in file names. On UNIX systems the value is ..

isAbsolute :: String → Bool

Is the argument an absolute name?

dirName :: String → String

Extracts the directory prefix of a given (Unix) file name. Returns "." if there is no prefix.

baseName :: String → String

Extracts the base name without directory prefix of a given (Unix) file name.

splitDirectoryBaseName :: String → (String,String)

Splits a (Unix) file name into the directory prefix and the base name. The directory prefix is "." if there is no real prefix in the name.

stripSuffix :: String → String

Strips a suffix (the last suffix starting with a dot) from a file name.

fileSuffix :: String → String

Yields the suffix (the last suffix starting with a dot) from given file name.

splitBaseName :: String → (String,String)

Splits a file name into prefix and suffix (the last suffix starting with a dot and the rest).

splitPath :: String → [String]

Splits a path string into list of directory names.

lookupFileInPath :: String → [String] → [String] → IO (Maybe String)

Looks up the first file with a possible suffix in a list of directories. Returns Nothing if such a file does not exist.

getFileInPath :: String → [String] → [String] → IO String

Gets the first file with a possible suffix in a list of directories. An error message is delivered if there is no such file.
A.2.13 Library FilePath

This library is a direct port of the Haskell library System.FilePath of Neil Mitchell.

Exported types:

\[
\text{type FilePath} = \text{String}
\]

Exported functions:

\[
\text{pathSeparator} :: \text{Char}
\]

\[
\text{pathSeparators} :: \text{String}
\]

\[
\text{isPathSeparator} :: \text{Char} \to \text{Bool}
\]

\[
\text{searchPathSeparator} :: \text{Char}
\]

\[
\text{isSearchPathSeparator} :: \text{Char} \to \text{Bool}
\]

\[
\text{extSeparator} :: \text{Char}
\]

\[
\text{isExtSeparator} :: \text{Char} \to \text{Bool}
\]

\[
\text{splitSearchPath} :: \text{String} \to [\text{String}]
\]

\[
\text{getSearchPath} :: \text{IO} [\text{String}]
\]

\[
\text{splitExtension} :: \text{String} \to (\text{String, String})
\]

\[
\text{takeExtension} :: \text{String} \to \text{String}
\]
replaceExtension :: String → String → String

(<.>) :: String → String → String

dropExtension :: String → String

addExtension :: String → String → String

hasExtension :: String → Bool

splitExtensions :: String → (String,String)

dropExtensions :: String → String

takeExtensions :: String → String

splitDrive :: String → (String,String)

joinDrive :: String → String → String

takeDrive :: String → String

dropDrive :: String → String

hasDrive :: String → Bool

isDrive :: String → Bool
splitFileName :: String → (String, String)

replaceFileName :: String → String → String

dropFileName :: String → String

takeFileName :: String → String

takeBaseName :: String → String

replaceBaseName :: String → String → String

hasTrailingPathSeparator :: String → Bool

addTrailingPathSeparator :: String → String

dropTrailingPathSeparator :: String → String

takeDirectory :: String → String

replaceDirectory :: String → String → String

combine :: String → String → String

(</>): String → String → String

splitPath :: String → [String]
splitDirectories :: String \rightarrow [String]

joinPath :: [String] \rightarrow String

equalFilePath :: String \rightarrow String \rightarrow Bool

makeRelative :: String \rightarrow String \rightarrow String

normalise :: String \rightarrow String

isValid :: String \rightarrow Bool

makeValid :: String \rightarrow String

isRelative :: String \rightarrow Bool

isAbsolute :: String \rightarrow Bool

A.2.14 Library Findall

Library with some operations for encapsulating search. Note that some of these operations are not fully declarative, i.e., the results depend on the order of evaluation and program rules. There are newer and better approaches the encapsulate search, in particular, set functions (see module SetFunctions), which should be used.

This library is included only for compatibility with PAKCS.

Exported functions:

getAllValues :: a \rightarrow IO [a]

Gets all values of an expression (currently, via an incomplete depth-first strategy). Conceptually, all values are computed on a copy of the expression, i.e., the evaluation of the expression does not share any results. Moreover, the evaluation suspends as long as the expression contains unbound variables. Similar to Prolog’s findall.
getSomeValue :: a → IO a

Gets a value of an expression (currently, via an incomplete depth-first strategy). The expression must have a value, otherwise the computation fails. Conceptually, the value is computed on a copy of the expression, i.e., the evaluation of the expression does not share any results. Moreover, the evaluation suspends as long as the expression contains unbound variables.

allValues :: a → [a]

Returns all values of an expression (currently, via an incomplete depth-first strategy). Conceptually, all values are computed on a copy of the expression, i.e., the evaluation of the expression does not share any results.

Note that this operation is not purely declarative since the ordering of the computed values depends on the ordering of the program rules.

someValue :: a → a

Returns some value for an expression (currently, via an incomplete depth-first strategy). If the expression has no value, the computation fails. Conceptually, the value is computed on a copy of the expression, i.e., the evaluation of the expression does not share any results.

Note that this operation is not purely declarative since the computed value depends on the ordering of the program rules. Thus, this operation should be used only if the expression has a single value.

allSolutions :: (a → Bool) → [a]

Returns all values satisfying a predicate, i.e., all arguments such that the predicate applied to the argument can be evaluated to True (currently, via an incomplete depth-first strategy).

Note that this operation is not purely declarative since the ordering of the computed values depends on the ordering of the program rules.

someSolution :: (a → Bool) → a

Returns some values satisfying a predicate, i.e., some argument such that the predicate applied to the argument can be evaluated to True (currently, via an incomplete depth-first strategy). If there is no value satisfying the predicate, the computation fails.

Note that this operation is not purely declarative since the ordering of the computed values depends on the ordering of the program rules. Thus, this operation should be used only if the predicate has a single solution.

A.2.15 Library Float

A collection of operations on floating point numbers.
Exported functions:

\( \text{pi} :: \text{Float} \)

The number pi.

\( (+.) :: \text{Float} \rightarrow \text{Float} \rightarrow \text{Float} \)

Addition on floats.

\( (-.) :: \text{Float} \rightarrow \text{Float} \rightarrow \text{Float} \)

Subtraction on floats.

\( (*) :: \text{Float} \rightarrow \text{Float} \rightarrow \text{Float} \)

Multiplication on floats.

\( (/.) :: \text{Float} \rightarrow \text{Float} \rightarrow \text{Float} \)

Division on floats.

\( (^.) :: \text{Float} \rightarrow \text{Int} \rightarrow \text{Float} \)

The value of \( a \ ^ \ b \) is \( a \) raised to the power of \( b \). Executes in \( O(\log b) \) steps.

\( \text{i2f} :: \text{Int} \rightarrow \text{Float} \)

Conversion function from integers to floats.

\( \text{truncate} :: \text{Float} \rightarrow \text{Int} \)

Conversion function from floats to integers. The result is the closest integer between the argument and 0.

\( \text{round} :: \text{Float} \rightarrow \text{Int} \)

Conversion function from floats to integers. The result is the nearest integer to the argument. If the argument is equidistant between two integers, it is rounded to the closest even integer value.

\( \text{recip} :: \text{Float} \rightarrow \text{Float} \)

Reciprocal

\( \text{sqrt} :: \text{Float} \rightarrow \text{Float} \)

Square root.

\( \text{log} :: \text{Float} \rightarrow \text{Float} \)

Natural logarithm.

\( \text{logBase} :: \text{Float} \rightarrow \text{Float} \rightarrow \text{Float} \)
Logarithm to arbitrary Base.

\[ \text{exp} :: \text{Float} \rightarrow \text{Float} \]
Natural exponent.

\[ \text{sin} :: \text{Float} \rightarrow \text{Float} \]
Sine.

\[ \text{cos} :: \text{Float} \rightarrow \text{Float} \]
Cosine.

\[ \text{tan} :: \text{Float} \rightarrow \text{Float} \]
Tangent.

\[ \text{asin} :: \text{Float} \rightarrow \text{Float} \]
Arc sine.

\[ \text{acos} :: \text{Float} \rightarrow \text{Float} \]

\[ \text{atan} :: \text{Float} \rightarrow \text{Float} \]
Arc tangent.

\[ \text{sinh} :: \text{Float} \rightarrow \text{Float} \]
Hyperbolic sine.

\[ \text{cosh} :: \text{Float} \rightarrow \text{Float} \]

\[ \text{tanh} :: \text{Float} \rightarrow \text{Float} \]
Hyperbolic tangent.

\[ \text{asinh} :: \text{Float} \rightarrow \text{Float} \]
Hyperbolic Arc sine.

\[ \text{acosh} :: \text{Float} \rightarrow \text{Float} \]

\[ \text{atanh} :: \text{Float} \rightarrow \text{Float} \]
Hyperbolic Arc tangent.

A.2.16 Library Function
This module provides some utility functions for function application.
Exported functions:

\textbf{fix} :: (a \rightarrow a) \rightarrow a

\textit{fix f} is the least fixed point of the function \textit{f}, i.e. the least defined \textit{x} such that \textit{f x} = \textit{x}.

\textbf{on} :: (a \rightarrow a \rightarrow b) \rightarrow (c \rightarrow a) \rightarrow c \rightarrow c \rightarrow b

(*) ‘on’ \textit{f} = \\textit{x} y \rightarrow f x * f y. Typical usage: \textbf{sortBy (compare ‘on‘ \textit{fst})}.

\textbf{first} :: (a \rightarrow b) \rightarrow (a,c) \rightarrow (b,c)

Apply a function to the first component of a tuple.

\textbf{second} :: (a \rightarrow b) \rightarrow (c,a) \rightarrow (c,b)

Apply a function to the second component of a tuple.

\textbf{(***)} :: (a \rightarrow b) \rightarrow (c \rightarrow d) \rightarrow (a,c) \rightarrow (b,d)

Apply two functions to the two components of a tuple.

\textbf{(&&&)} :: (a \rightarrow b) \rightarrow (a \rightarrow c) \rightarrow a \rightarrow (b,c)

Apply two functions to a value and returns a tuple of the results.

\textbf{both} :: (a \rightarrow b) \rightarrow (a,a) \rightarrow (b,b)

Apply a function to both components of a tuple.

A.2.17 Library Function Inversion

This module provides some utility functions for inverting functions.

Exported functions:

\textbf{invf1} :: (a \rightarrow b) \rightarrow b \rightarrow a

Inverts a unary function.

\textbf{invf2} :: (a \rightarrow b \rightarrow c) \rightarrow c \rightarrow (a,b)

Inverts a binary function.

\textbf{invf3} :: (a \rightarrow b \rightarrow c \rightarrow d) \rightarrow d \rightarrow (a,b,c)

Inverts a ternary function.

\textbf{invf4} :: (a \rightarrow b \rightarrow c \rightarrow d \rightarrow e) \rightarrow e \rightarrow (a,b,c,d)

Inverts a function of arity 4.

\textbf{invf5} :: (a \rightarrow b \rightarrow c \rightarrow d \rightarrow e \rightarrow f) \rightarrow f \rightarrow (a,b,c,d,e)

Inverts a function of arity 5.
A.2.18 Library GetOpt

This Module is a modified version of the Module System.Console:GetOpt by Sven Panne from the
ghc-base package it has been adapted for Curry by Bjoern Peemoeller

OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING
NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFT-
WARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

Exported types:

data ArgOrder

  Exported constructors:
  - RequireOrder :: ArgOrder a
  - Permute :: ArgOrder a
  - ReturnInOrder :: (String → a) → ArgOrder a

data OptDescr

  Exported constructors:
  - Option :: String → [String] → (ArgDescr a) → String → OptDescr a

data ArgDescr
Exported constructors:

- NoArg :: a → ArgDescr a
- ReqArg :: (String → a) → String → ArgDescr a
- OptArg :: (Maybe String → a) → String → ArgDescr a

Exported functions:

usageInfo :: String → [OptDescr a] → String

gOpt :: ArgOrder a → [OptDescr a] → [String] → ([a],[String],[String])

gOpt' :: ArgOrder a → [OptDescr a] → [String] → ([a],[String],[String],[String])

A.2.19 Library Global

Library for handling global entities. A global entity has a name declared in the program. Its value can be accessed and modified by IO actions. Furthermore, global entities can be declared as persistent so that their values are stored across different program executions. Currently, it is still experimental so that its interface might be slightly changed in the future.

A global entity \( g \) with an initial value \( v \) of type \( t \) must be declared by:

\[
g :: Global t  
g = \text{global } v \text{ spec}
\]

Here, the type \( t \) must not contain type variables and \( \text{spec} \) specifies the storage mechanism for the global entity (see type \( \text{GlobalSpec} \)).

Exported types:

data Global

The abstract type of a global entity.

Exported constructors:

data GlobalSpec

The storage mechanism for the global entity.

Exported constructors:
• Temporary :: GlobalSpec
  Temporary
  – the global value exists only during a single execution of a program

• Persistent :: String → GlobalSpec
  Persistent f
  – the global value is stored persistently in file f (which is created and initialized if it does not exists)

Exported functions:

global :: a → GlobalSpec → Global a

  global is only used for the declaration of a global value and should not be used elsewhere.
  In the future, it might become a keyword.

readGlobal :: Global a → IO a

  Reads the current value of a global.

safeReadGlobal :: Global a → a → IO a

  Safely reads the current value of a global. If readGlobal fails (e.g., due to a corrupted persistent storage), the global is re-initialized with the default value given as the second argument.

writeGlobal :: Global a → a → IO ()

  Updates the value of a global. The value is evaluated to a ground constructor term before it is updated.

A.2.20 Library Integer

A collection of common operations on integer numbers. Most operations make no assumption on the precision of integers. Operation bitNot is necessarily an exception.

Exported functions:

(^) :: Int → Int → Int

  The value of a ^ b is a raised to the power of b. Fails if b < 0. Executes in O(log b) steps.

pow :: Int → Int → Int

  The value of pow a b is a raised to the power of b. Fails if b < 0. Executes in O(log b) steps.

ilog :: Int → Int
The value of \( \text{ilog n} \) is the floor of the logarithm in the base 10 of \( n \). Fails if \( n \leq 0 \). For positive integers, the returned value is 1 less the number of digits in the decimal representation of \( n \).

\( \text{isqrt :: Int } \to \text{Int} \)

The value of \( \text{isqrt n} \) is the floor of the square root of \( n \). Fails if \( n < 0 \). Executes in \( O(\log n) \) steps, but there must be a better way.

\( \text{factorial :: Int } \to \text{Int} \)

The value of \( \text{factorial n} \) is the factorial of \( n \). Fails if \( n < 0 \).

\( \text{binomial :: Int } \to \text{Int } \to \text{Int} \)

The value of \( \text{binomial n m} \) is \( \frac{n(n-1)...(n-m+1)}{m(m-1)...1} \). Fails if \( m \leq 0 \) or \( n < m \).

\( \text{abs :: Int } \to \text{Int} \)

The value of \( \text{abs n} \) is the absolute value of \( n \).

\( \text{max3 :: a } \to \text{a } \to \text{a } \to \text{a} \)

Returns the maximum of the three arguments.

\( \text{min3 :: a } \to \text{a } \to \text{a } \to \text{a} \)

Returns the minimum of the three arguments.

\( \text{maxlist :: [a] } \to \text{a} \)

Returns the maximum of a list of integer values. Fails if the list is empty.

\( \text{minlist :: [a] } \to \text{a} \)

Returns the minimum of a list of integer values. Fails if the list is empty.

\( \text{bitTrunc :: Int } \to \text{Int } \to \text{Int} \)

The value of \( \text{bitTrunc n m} \) is the value of the \( n \) least significant bits of \( m \).

\( \text{bitAnd :: Int } \to \text{Int } \to \text{Int} \)

Returns the bitwise AND of the two arguments.

\( \text{bitOr :: Int } \to \text{Int } \to \text{Int} \)

Returns the bitwise inclusive OR of the two arguments.

\( \text{bitNot :: Int } \to \text{Int} \)

Returns the bitwise NOT of the argument. Since integers have unlimited precision, only the 32 least significant bits are computed.
bitXor :: Int → Int → Int
Returns the bitwise exclusive OR of the two arguments.

even :: Int → Bool
Returns whether an integer is even

odd :: Int → Bool
Returns whether an integer is odd

A.2.21 Library IO
Library for IO operations like reading and writing files that are not already contained in the prelude.

Exported types:

data Handle

   The abstract type of a handle for a stream.

   Exported constructors:

data IOMode

   The modes for opening a file.

   Exported constructors:
   • ReadMode :: IOMode
   • WriteMode :: IOMode
   • AppendMode :: IOMode

data SeekMode

   The modes for positioning with hSeek in a file.

   Exported constructors:
   • AbsoluteSeek :: SeekMode
   • RelativeSeek :: SeekMode
   • SeekFromEnd :: SeekMode
Exported functions:

stdin :: Handle

  Standard input stream.

stdout :: Handle

  Standard output stream.

stderr :: Handle

  Standard error stream.

openFile :: String → IOMode → IO Handle

  Opens a file in specified mode and returns a handle to it.

hClose :: Handle → IO ()

  Closes a file handle and flushes the buffer in case of output file.

hFlush :: Handle → IO ()

  Flushes the buffer associated to handle in case of output file.

hIsEOF :: Handle → IO Bool

  Is handle at end of file?

isEOF :: IO Bool

  Is standard input at end of file?

hSeek :: Handle → SeekMode → Int → IO ()

  Set the position of a handle to a seekable stream (e.g., a file). If the second argument is AbsoluteSeek, SeekFromEnd, or RelativeSeek, the position is set relative to the beginning of the file, to the end of the file, or to the current position, respectively.

hWaitForInput :: Handle → Int → IO Bool

  Waits until input is available on the given handle. If no input is available within t milliseconds, it returns False, otherwise it returns True.

hWaitForInputs :: [Handle] → Int → IO Int

  Waits until input is available on some of the given handles. If no input is available within t milliseconds, it returns -1, otherwise it returns the index of the corresponding handle with the available data.

hWaitForInputOrMsg :: Handle → [a] → IO (Either Handle [a])
Waits until input is available on a given handles or a message in the message stream. Usually, the message stream comes from an external port. Thus, this operation implements a committed choice over receiving input from an IO handle or an external port.

*Note that the implementation of this operation works only with Sicstus-Prolog 3.8.5 or higher (due to a bug in previous versions of Sicstus-Prolog).*

\[ \text{hWaitForInputsOrMsg :: [Handle] \to [a] \to IO (Either Int [a])} \]

Waits until input is available on some of the given handles or a message in the message stream. Usually, the message stream comes from an external port. Thus, this operation implements a committed choice over receiving input from IO handles or an external port.

*Note that the implementation of this operation works only with Sicstus-Prolog 3.8.5 or higher (due to a bug in previous versions of Sicstus-Prolog).*

\[ \text{hReady :: Handle \to IO Bool} \]

Checks whether an input is available on a given handle.

\[ \text{hGetChar :: Handle \to IO Char} \]

Reads a character from an input handle and returns it. Throws an error if the end of file has been reached.

\[ \text{hGetLine :: Handle \to IO String} \]

Reads a line from an input handle and returns it. Throws an error if the end of file has been reached while reading the *first* character. If the end of file is reached later in the line, it is treated as a line terminator and the (partial) line is returned.

\[ \text{hGetContents :: Handle \to IO String} \]

Reads the complete contents from an input handle and closes the input handle before returning the contents.

\[ \text{getContents :: IO String} \]

Reads the complete contents from the standard input stream until EOF.

\[ \text{hPutChar :: Handle \to Char \to IO ()} \]

Puts a character to an output handle.

\[ \text{hPutStr :: Handle \to String \to IO ()} \]

Puts a string to an output handle.

\[ \text{hPutStrLn :: Handle \to String \to IO ()} \]

Puts a string with a newline to an output handle.
hPrint :: Handle → a → IO ()

Converts a term into a string and puts it to an output handle.

hIsReadable :: Handle → IO Bool

Is the handle readable?

hIsWritable :: Handle → IO Bool

Is the handle writable?

hIsTerminalDevice :: Handle → IO Bool

Is the handle connected to a terminal?

A.2.22 Library IOExts

Library with some useful extensions to the IO monad.

Exported types:

data IORef

Mutable variables containing values of some type. The values are not evaluated when they are assigned to an IORef.

Exported constructors:

Exported functions:

data IORef

data IORef

data IORef

data IORef

execCmd :: String → IO (Handle,Handle,Handle)

Executes a command with a new default shell process. The standard I/O streams of the new process (stdin,stdout,stderr) are returned as handles so that they can be explicitly manipulated. They should be closed with IO.hClose since they are not closed automatically when the process terminates.

evalCmd :: String → [String] → String → IO (Int,String,String)

Executes a command with the given arguments as a new default shell process and provides the input via the process’ stdin input stream. The exit code of the process and the contents written to the standard I/O streams stdout and stderr are returned.

connectToCommand :: String → IO Handle

Executes a command with a new default shell process. The input and output streams of the new process is returned as one handle which is both readable and writable. Thus, writing to the handle produces input to the process and output from the process can be retrieved by reading from this handle. The handle should be closed with IO.hClose since they are not closed automatically when the process terminates.
readCompleteFile :: String → IO String

An action that reads the complete contents of a file and returns it. This action can be used instead of the (lazy) readFile action if the contents of the file might be changed.

updateFile :: (String → String) → String → IO ()

An action that updates the contents of a file.

exclusiveIO :: String → IO a → IO a

Forces the exclusive execution of an action via a lock file. For instance, (exclusiveIO "myaction.lock" act) ensures that the action "act" is not executed by two processes on the same system at the same time.

setAssoc :: String → String → IO ()

Defines a global association between two strings. Both arguments must be evaluable to ground terms before applying this operation.

getAssoc :: String → IO (Maybe String)

Gets the value associated to a string. Nothing is returned if there does not exist an associated value.

newIORef :: a → IO (IORef a)

Creates a new IORef with an initial value.

readIORef :: IORef a → IO a

Reads the current value of an IORef.

writeIORef :: IORef a → a → IO ()

Updates the value of an IORef.

modifyIORef :: IORef a → (a → a) → IO ()

Modify the value of an IORef.

A.2.23 Library List

Library with some useful operations on lists.

Exported functions:

elemIndex :: a → [a] → Maybe Int

Returns the index i of the first occurrence of an element in a list as (Just i), otherwise Nothing is returned.

elemIndices :: a → [a] → [Int]
Returns the list of indices of occurrences of an element in a list.

\[
\text{find} :: (a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow \text{Maybe}\ a
\]

Returns the first element \(e\) of a list satisfying a predicate as \((\text{Just}\ e)\), otherwise \text{Nothing} is returned.

\[
\text{findIndex} :: (a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow \text{Maybe}\ \text{Int}
\]

Returns the index \(i\) of the first occurrences of a list element satisfying a predicate as \((\text{Just}\ i)\), otherwise \text{Nothing} is returned.

\[
\text{findIndices} :: (a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow [\text{Int}]
\]

Returns the list of indices of list elements satisfying a predicate.

\[
\text{nub} :: [a] \rightarrow [a]
\]

Removes all duplicates in the argument list.

\[
\text{nubBy} :: (a \rightarrow a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow [a]
\]

Removes all duplicates in the argument list according to an equivalence relation.

\[
\text{delete} :: a \rightarrow [a] \rightarrow [a]
\]

Deletes the first occurrence of an element in a list.

\[
\text{deleteBy} :: (a \rightarrow a \rightarrow \text{Bool}) \rightarrow a \rightarrow [a] \rightarrow [a]
\]

Deletes the first occurrence of an element in a list according to an equivalence relation.

\[
(\\setminus\) :: [a] \rightarrow [a] \rightarrow [a]
\]

Computes the difference of two lists.

\[
\text{union} :: [a] \rightarrow [a] \rightarrow [a]
\]

Computes the union of two lists.

\[
\text{unionBy} :: (a \rightarrow a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow [a] \rightarrow [a]
\]

Computes the union of two lists according to the given equivalence relation

\[
\text{intersect} :: [a] \rightarrow [a] \rightarrow [a]
\]

Computes the intersection of two lists.

\[
\text{intersectBy} :: (a \rightarrow a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow [a] \rightarrow [a]
\]

Computes the intersection of two lists according to the given equivalence relation

\[
\text{intersperse} :: a \rightarrow [a] \rightarrow [a]
\]
Puts a separator element between all elements in a list.
Example: \(\text{intersperse } 9 \ [1,2,3,4] \) = \([1,9,2,9,3,9,4]\)

\[\text{intersperse} :: [a] \rightarrow [[a]] \rightarrow [a]\]

\[\text{intersperse} \ x \ xss \] is equivalent to \(\text{concat} \ (\text{intersperse} \ x \ xss)\). It inserts the list \(x\) in between the lists in \(xss\) and concatenates the result.

\[\text{intercalate} :: [[a]] \rightarrow [[a]]\]

\[\text{intercalate} \ xs \ xss \] is equivalent to \(\text{concat} \ (\text{intersperse} \ xs \ xss)\). It inserts the list \(xs\) in between the lists in \(xss\) and concatenates the result.

\[\text{transpose} :: [[a]] \rightarrow [[a]]\]

Transposes the rows and columns of the argument.
Example: \(\text{transpose} \ ([[1,2,3],[4,5,6]]) = [[1,4],[2,5],[3,6]]\)

\[\text{diagonal} :: [[a]] \rightarrow [a]\]

Diagonalization of a list of lists. Fairly merges (possibly infinite) list of (possibly infinite) lists.

\[\text{permutations} :: [a] \rightarrow [[a]]\]

Returns the list of all permutations of the argument.

\[\text{partition} :: (a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow ([a],[a])\]

Partitions a list into a pair of lists where the first list contains those elements that satisfy the predicate argument and the second list contains the remaining arguments.
Example: \(\text{partition} \ (<4) \ [8,1,5,2,4,3]) = ([1,2,3],[8,5,4])\)

\[\text{group} :: [a] \rightarrow [[a]]\]

Splits the list argument into a list of lists of equal adjacent elements.
Example: \(\text{group} \ [1,2,2,3,3,3,4]) = [[1],[2,2],[3,3,3],[4]]\)

\[\text{groupBy} :: (a \rightarrow a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow [[a]]\]

Splits the list argument into a list of lists of related adjacent elements.

\[\text{splitOn} :: [a] \rightarrow [a] \rightarrow [[a]]\]

Breaks the second list argument into pieces separated by the first list argument, consuming the delimiter. An empty delimiter is invalid, and will cause an error to be raised.

\[\text{split} :: (a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow [[a]]\]

Splits a list into components delimited by separators, where the predicate returns True for a separator element. The resulting components do not contain the separators. Two adjacent separators result in an empty component in the output.

\[\text{split} (==a) "aabbaca" = ["","","bb","c",""]\]

\[\text{split} (==a) "" = [""]\]
\[\text{inits} \colon [a] \rightarrow [[a]]\]

Returns all initial segments of a list, starting with the shortest. Example: \[\text{inits} [1,2,3] = [[],[1],[1,2],[1,2,3]]\]

\[\text{tails} \colon [a] \rightarrow [[a]]\]

Returns all final segments of a list, starting with the longest. Example: \[\text{tails} [1,2,3] = [[1,2,3],[2,3],[3],[\]]\]

\[\text{replace} :: a \rightarrow \text{Int} \rightarrow [a] \rightarrow [a]\]

Replaces an element in a list.

\[\text{isPrefixOf} :: [a] \rightarrow [a] \rightarrow \text{Bool}\]

Checks whether a list is a prefix of another.

\[\text{isSuffixOf} :: [a] \rightarrow [a] \rightarrow \text{Bool}\]

Checks whether a list is a suffix of another.

\[\text{isInfixOf} :: [a] \rightarrow [a] \rightarrow \text{Bool}\]

Checks whether a list is contained in another.

\[\text{sortBy} :: (a \rightarrow a \rightarrow \text{Bool}) \rightarrow [a] \rightarrow [a]\]

Sorts a list w.r.t. an ordering relation by the insertion method.

\[\text{insertBy} :: (a \rightarrow a \rightarrow \text{Bool}) \rightarrow a \rightarrow [a] \rightarrow [a]\]

Inserts an object into a list according to an ordering relation.

\[\text{last} :: [a] \rightarrow a\]

Returns the last element of a non-empty list.

\[\text{init} :: [a] \rightarrow [a]\]

Returns the input list with the last element removed.

\[\text{sum} :: [\text{Int}] \rightarrow \text{Int}\]

Returns the sum of a list of integers.

\[\text{product} :: [\text{Int}] \rightarrow \text{Int}\]

Returns the product of a list of integers.

\[\text{maximum} :: [a] \rightarrow a\]

Returns the maximum of a non-empty list.

\[\text{maximumBy} :: (a \rightarrow a \rightarrow \text{Ordering}) \rightarrow [a] \rightarrow a\]
Returns the maximum of a non-empty list according to the given comparison function

\[ \text{maximum} :: [a] \rightarrow a \]

Returns the minimum of a non-empty list.

\[ \text{minimum} :: (a \rightarrow a \rightarrow \text{Ordering}) \rightarrow [a] \rightarrow a \]

Returns the minimum of a non-empty list according to the given comparison function.

\[ \text{scanl} :: (a \rightarrow b \rightarrow a) \rightarrow a \rightarrow [b] \rightarrow [a] \]

\[ \text{scanl} \] is similar to \( \text{foldl} \), but returns a list of successive reduced values from the left:

\[ \text{scanl} f z [x1, x2, \ldots] == [z, z f x1, (z f x1) f x2, \ldots] \]

\[ \text{scanl1} :: (a \rightarrow a \rightarrow a) \rightarrow [a] \rightarrow [a] \]

\[ \text{scanl1} \] is a variant of \( \text{scanl} \) that has no starting value argument:

\[ \text{scanl1} f [x1, x2, \ldots] == [x1, x1 f x2, \ldots] \]

\[ \text{scanr} :: (a \rightarrow b \rightarrow b) \rightarrow b \rightarrow [a] \rightarrow [b] \]

\[ \text{scanr} \] is the right-to-left dual of \( \text{scanl} \).

\[ \text{scanr1} :: (a \rightarrow a \rightarrow a) \rightarrow [a] \rightarrow [a] \]

\[ \text{scanr1} \] is a variant of \( \text{scanr} \) that has no starting value argument.

\[ \text{mapAccumL} :: (a \rightarrow b \rightarrow (a,c)) \rightarrow a \rightarrow [b] \rightarrow (a,[c]) \]

The \( \text{mapAccumL} \) function behaves like a combination of \( \text{map} \) and \( \text{foldl} \); it applies a function to each element of a list, passing an accumulating parameter from left to right, and returning a final value of this accumulator together with the new list.

\[ \text{mapAccumR} :: (a \rightarrow b \rightarrow (a,c)) \rightarrow a \rightarrow [b] \rightarrow (a,[c]) \]

The \( \text{mapAccumR} \) function behaves like a combination of \( \text{map} \) and \( \text{foldr} \); it applies a function to each element of a list, passing an accumulating parameter from right to left, and returning a final value of this accumulator together with the new list.

\[ \text{cycle} :: [a] \rightarrow [a] \]

Builds an infinite list from a finite one.

\[ \text{unfoldr} :: (a \rightarrow \text{Maybe} (b,a)) \rightarrow a \rightarrow [b] \]

Builds a list from a seed value.

### A.2.24 Library Maybe

Library with some useful functions on the \text{Maybe} datatype.
Exported functions:

isJust :: Maybe a → Bool

Return True iff the argument is of the form Just _.

isNothing :: Maybe a → Bool

Return True iff the argument is of the form Nothing.

fromJust :: Maybe a → a

Extract the argument from the Just constructor and throw an error if the argument is Nothing.

fromMaybe :: a → Maybe a → a

Extract the argument from the Just constructor or return the provided default value if the argument is Nothing.

listToMaybe :: [a] → Maybe a

Return Nothing on an empty list or Just x where x is the first list element.

maybeToList :: Maybe a → [a]

Return an empty list for Nothing or a singleton list for Just x.

catMaybes :: [Maybe a] → [a]

Return the list of all Just values.

mapMaybe :: (a → Maybe b) → [a] → [b]

Apply a function which may throw out elements using the Nothing constructor to a list of elements.

(>>>) :: Maybe a → (a → Maybe b) → Maybe b

Monadic bind for Maybe. Maybe can be interpreted as a monad where Nothing is interpreted as the error case by this monadic binding.

sequenceMaybe :: [Maybe a] → Maybe [a]

Monadic sequence for Maybe.

mapMMaybe :: (a → Maybe b) → [a] → Maybe [b]

Monadic map for Maybe.

mplus :: Maybe a → Maybe a → Maybe a

Combine two Maybes, returning the first Just value, if any.
A.2.25 Library NamedSocket

Library to support network programming with sockets that are addressed by symbolic names. In contrast to raw sockets (see library Socket), this library uses the Curry Port Name Server to provide sockets that are addressed by symbolic names rather than numbers. In standard applications, the server side uses the operations `listenOn` and `socketAccept` to provide some service on a named socket, and the client side uses the operation `connectToSocket` to request a service.

Exported types:

data Socket

Abstract type for named sockets.

*Exported constructors:*

Exported functions:

`listenOn :: String → IO Socket`

Creates a server side socket with a symbolic name.

`socketAccept :: Socket → IO (String,Handle)`

Returns a connection of a client to a socket. The connection is returned as a pair consisting of a string identifying the client (the format of this string is implementation-dependent) and a handle to a stream communication with the client. The handle is both readable and writable.

`waitForSocketAccept :: Socket → Int → IO (Maybe (String,Handle))`

Waits until a connection of a client to a socket is available. If no connection is available within the time limit, it returns Nothing, otherwise the connection is returned as a pair consisting of a string identifying the client (the format of this string is implementation-dependent) and a handle to a stream communication with the client.

`sClose :: Socket → IO ()`

Closes a server socket.

`socketName :: Socket → String`

Returns a the symbolic name of a named socket.

`connectToSocketRepeat :: Int → IO a → Int → String → IO (Maybe Handle)`

Waits for connection to a Unix socket with a symbolic name. In contrast to `connectToSocket`, this action waits until the socket has been registered with its symbolic name.
connectToSocketWait :: String → IO Handle

  Waits for connection to a Unix socket with a symbolic name and return the handle of
  the connection. This action waits (possibly forever) until the socket with the symbolic
  name is registered.

connectToSocket :: String → IO Handle

  Creates a new connection to an existing(!) Unix socket with a symbolic name. If the
  symbolic name is not registered, an error is reported.

A.2.26 Library Nat

Library defining natural numbers in Peano representation and some operations on this representa-

Exported types:

data Nat

  Natural numbers defined in Peano representation.

  Exported constructors:
  • Z :: Nat
  • S :: Nat → Nat

Exported functions:

fromNat :: Nat → Int

  Transforms a natural number into a standard integer.

toNat :: Int → Nat

  Transforms a standard integer into a natural number.

add :: Nat → Nat → Nat

  Addition on natural numbers.

sub :: Nat → Nat → Nat

  Subtraction defined by reversing addition.

mul :: Nat → Nat → Nat

  Multiplication on natural numbers.

leq :: Nat → Nat → Bool
A.2.27  Library Parser

Library with functional logic parser combinators.

Exported types:

```haskell
type Parser a = [a] \to [a]

type ParserRep a b = a \to [b] \to [b]
```

Exported functions:

```haskell
(<|>) :: ([a] \to [a]) \to ([a] \to [a]) \to [a] \to [a]

Combines two parsers without representation in an alternative manner.

(<||>) :: (a \to [b] \to [b]) \to (a \to [b] \to [b]) \to a \to [b] \to [b]

Combines two parsers with representation in an alternative manner.

(<*>) :: ([a] \to [a]) \to ([a] \to [a]) \to [a] \to [a]

Combines two parsers (with or without representation) in a sequential manner.

(>>>) :: ([a] \to [a]) \to b \to b \to [a] \to [a]

Attaches a representation to a parser without representation.

empty :: [a] \to [a]

The empty parser which recognizes the empty word.

terminal :: a \to [a] \to [a]

A parser recognizing a particular terminal symbol.

satisfy :: (a \to Bool) \to a \to [a] \to [a]

A parser (with representation) recognizing a terminal satisfying a given predicate.

star :: (a \to [b] \to [b]) \to [a] \to [b] \to [b]

A star combinator for parsers. The returned parser repeats zero or more times a parser p with representation and returns the representation of all parsers in a list.

some :: (a \to [b] \to [b]) \to [a] \to [b] \to [b]

A some combinator for parsers. The returned parser repeats the argument parser (with representation) at least once.
A.2.28 Library Pretty

This library provides pretty printing combinators. The interface is that of Daan Leijen’s library linear-time, bounded implementation by Olaf Chitil. Note that the implementation of fill and fillBreak is not linear-time bounded. Support of ANSI escape codes for formatting and colorisation of documents in text terminals (see https://en.wikipedia.org/wiki/ANSIescapecode)

Exported types:

data Doc

    The abstract data type Doc represents pretty documents.

Exported constructors:

Exported functions:

pPrint :: Doc → String

    Standard printing with a column length of 80.

empty :: Doc

    The empty document

isEmpty :: Doc → Bool

    Is the document empty?

text :: String → Doc

    The document (text s) contains the literal string s. The string shouldn’t contain any newline (\n) characters. If the string contains newline characters, the function string should be used.

linesep :: String → Doc

    The document (linesep s) advances to the next line and indents to the current nesting level. Document (linesep s) behaves like (text s) if the line break is undone by group.

hardline :: Doc

    The document hardline advances to the next line and indents to the current nesting level. hardline cannot be undone by group.

line :: Doc

    The document line advances to the next line and indents to the current nesting level. Document line behaves like (text " ") if the line break is undone by group.

linebreak :: Doc
The document `linebreak` advances to the next line and indents to the current nesting level. Document `linebreak` behaves like `(text "")` if the line break is undone by `group`.

`softline :: Doc`

The document `softline` behaves like `space` if the resulting output fits the page, otherwise it behaves like `line`. `softline = group line`

`softbreak :: Doc`

The document `softbreak` behaves like `(text "")` if the resulting output fits the page, otherwise it behaves like `line`. `softbreak = group linebreak`

`group :: Doc → Doc`

The combinator `group` is used to specify alternative layouts. The document `(group x)` undoes all line breaks in document `x`. The resulting line is added to the current line if that fits the page. Otherwise, the document `x` is rendered without any changes.

`nest :: Int → Doc → Doc`

The document `(nest i d)` renders document `d` with the current indentation level increased by `i` (See also `hang`, `align` and `indent`).

```
nest 2 (text "hello" $$ text "world") $$ text "!
```

outputs as:

```
hello
    world
! 
```

`hang :: Int → Doc → Doc`

The combinator `hang` implements hanging indentation. The document `(hang i d)` renders document `d` with a nesting level set to the current column plus `i`. The following example uses hanging indentation for some text:

```
test = hang 4
    (fillSep
        (map text
            (words "the hang combinator indents these words !")))
```

Which lays out on a page with a width of 20 characters as:

```
the hang combinator
    indents these
    words ! 
```
The hang combinator is implemented as:

\[
\text{hang } i \ x = \text{align} \ (\text{nest } i \ x)
\]

\text{align} :: \text{Doc} \to \text{Doc}

The document \((\text{align } d)\) renders document \(d\) with the nesting level set to the current column. It is used for example to implement \(\text{hang}'\).

As an example, we will put a document right above another one, regardless of the current nesting level:

\[
x \ $$ \ y = \text{align} \ (x \ $$ \ y)
\]
\[
\text{test} \ = \ \text{text} \ "\text{hi}" \ <+> (\text{text} \ "\text{nice}" \ $$ \ \text{text} \ "\text{world}")
\]

which will be layed out as:

\[
\begin{align*}
\text{hi} & \quad \text{nice} \\
& \quad \text{world}
\end{align*}
\]

\text{indent} :: \text{Int} \to \text{Doc} \to \text{Doc}

The document \((\text{indent } i \ d)\) indents document \(d\) with \(i\) spaces.

\[
\text{test} \ = \ \text{indent} \ 4 \ (\text{fillSep} \ (\text{map} \ \text{text} \\
\quad \ (\text{words} \ "\text{the indent combinator indents these words!}")))
\]

Which lays out with a page width of 20 as:

\[
\begin{align*}
\text{the indent} \\
\text{combinator} \\
\text{indents these} \\
\text{words!}
\end{align*}
\]

\text{combine} :: \text{Doc} \to \text{Doc} \to \text{Doc} \to \text{Doc}

The document \((\text{combine } c \ d1 \ d2)\) combines document \(d1\) and \(d2\) with document \(c\) in between using \((<>\)) with identity \text{empty}. Thus, the following equations hold.

\[
\begin{align*}
\text{combine } c \ d1 \ & \text{ empty} = d1 \\
\text{combine } c \ \text{empty} \ d2 \ & = d2 \\
\text{combine } c \ d1 \ d2 \ & = d1 \ <> \ c \ <> \ d2 \ \text{if neither } d1 \ \text{nor} \ d2 \ \text{are empty}
\end{align*}
\]

\((<>\)) :: \text{Doc} \to \text{Doc} \to \text{Doc}
The document \((x <> y)\) concatenates document \(x\) and document \(y\). It is an associative operation having empty as a left and right unit.

\((<+>) :: \text{Doc} \to \text{Doc} \to \text{Doc}\)

The document \((x <+> y)\) concatenates document \(x\) and \(y\) with a space in between with identity empty.

\(($$) :: \text{Doc} \to \text{Doc} \to \text{Doc}\)

The document \((x $$ y)\) concatenates document \(x\) and \(y\) with a line in between with identity empty.

\((<$+$$>) :: \text{Doc} \to \text{Doc} \to \text{Doc}\)

The document \((x <$+$$> y)\) concatenates document \(x\) and \(y\) with a blank line in between with identity empty.

\((</>>) :: \text{Doc} \to \text{Doc} \to \text{Doc}\)

The document \((x </> y)\) concatenates document \(x\) and \(y\) with a softline in between with identity empty. This effectively puts \(x\) and \(y\) either next to each other (with a space in between) or underneath each other.

\((<$$>) :: \text{Doc} \to \text{Doc} \to \text{Doc}\)

The document \((x <$$ y)\) concatenates document \(x\) and \(y\) with a linebreak in between with identity empty.

\((<</>) :: \text{Doc} \to \text{Doc} \to \text{Doc}\)

The document \((x <</ y)\) concatenates document \(x\) and \(y\) with a softbreak in between with identity empty. This effectively puts \(x\) and \(y\) either right next to each other or underneath each other.

\((<$$!$$>) :: \text{Doc} \to \text{Doc} \to \text{Doc}\)

The document \((x <$$$ y)\) concatenates document \(x\) and \(y\) with a hardline in between with identity empty. This effectively puts \(x\) and \(y\) underneath each other.

\(\text{compose} :: (\text{Doc} \to \text{Doc} \to \text{Doc}) \to [\text{Doc}] \to \text{Doc}\)

The document \((\text{compose} f \; xs)\) concatenates all documents \(xs\) with function \(f\). Function \(f\) should be like \((<+>)\), \(($$)\) and so on.

\(\text{hsep} :: [\text{Doc}] \to \text{Doc}\)

The document \((\text{hsep} \; xs)\) concatenates all documents \(xs\) horizontally with \((<+>)\).

\(\text{vsep} :: [\text{Doc}] \to \text{Doc}\)

The document \((\text{vsep} \; xs)\) concatenates all documents \(xs\) vertically with \(($$)\). If a group undoes the line breaks inserted by \(\text{vsep}\), all documents are separated with a space.
someText = map text (words ("text to lay out"))

test = text "some" <+> vsep someText

This is layed out as:

some text
to
lay
out

The align combinator can be used to align the documents under their first element:

test = text "some" <+> align (vsep someText)

This is printed as:

some text
to
lay
out

vsepBlank :: [Doc] → Doc

The document vsep xs concatenates all documents xs vertically with ($+$). If a group undoes the line breaks inserted by vsepBlank, all documents are separated with a space.

fillSep :: [Doc] → Doc

The document (fillSep xs) concatenates documents xs horizontally with ($/>) as long as its fits the page, then inserts a line and continues doing that for all documents in xs.

fillSep xs = foldr ($/> empty xs

sep :: [Doc] → Doc

The document (sep xs) concatenates all documents xs either horizontally with ($+/), if it fits the page, or vertically with ($$). sep xs = group (vsep xs

hcat :: [Doc] → Doc

The document (hcat xs) concatenates all documents xs horizontally with ($/).

vcat :: [Doc] → Doc

The document (vcat xs) concatenates all documents xs vertically with ($$$). If a group undoes the line breaks inserted by vcat, all documents are directly concatenated.

fillCat :: [Doc] → Doc
The document \((\text{fillCat } xs)\) concatenates documents \(xs\) horizontally with \((<//>)\) as long as its fits the page, than inserts a \textbf{linebreak} and continues doing that for all documents in \(xs\). \textbf{fillCat } xs = foldr \((<//>)\) empty \(xs\)

\[
\text{cat :: [Doc] \to Doc}
\]

The document \((\text{cat } xs)\) concatenates all documents \(xs\) either horizontally with \((<>\)), if it fits the page, or vertically with \((<$$>\)). \text{cat } xs = \text{group (vcat } xs)\)

\[
\text{punctuate :: Doc \to [Doc] \to [Doc]}
\]

\((\text{punctuate } p \ x s)\) concatenates all documents \(xs\) with document \(p\) except for the last document.

\[
\text{someText = map text ["words","in","a","tuple"]}
\]
\[
\text{test = parens (align (cat (punctuate comma someText)))}
\]

This is layed out on a page width of 20 as:

\((\text{words, in, a, tuple})\)

But when the page width is 15, it is layed out as:

\((\text{words, in, a, tuple})\)

(If you want put the commas in front of their elements instead of at the end, you should use \textbf{tupled} or, in general, \textbf{encloseSep}.)

\[
\text{encloseSep :: Doc \to Doc \to Doc \to [Doc] \to Doc}
\]

The document \((\text{encloseSep } l \ r \ s \ x s)\) concatenates the documents \(xs\) seperated by \(s\) and encloses the resulting document by \(l\) and \(r\). The documents are rendered horizon-tally if that fits the page. Otherwise they are aligned vertically. All seperators are put in front of the elements.

For example, the combinator \textbf{list} can be defined with \textbf{encloseSep}:

\[
\text{list } xs = \text{encloseSep lbracket rbracket comma } xs
\]
\[
\text{test = text "list" <+> (list (map int [10,200,3000]))}
\]

Which is layed out with a page width of 20 as:

\[
\text{list [10,200,3000]}
\]
But when the page width is 15, it is layed out as:

```haskell
list [10,
     ,200,
     ,3000]
```

\[\text{encloseSepSpaced :: Doc \to Doc \to Doc \to [Doc] \to Doc}\]

The document \((\text{encloseSepSpaced} \, l \, r \, s \, xs)\) concatenates the documents \(xs\) seperated by \(s\) and encloses the resulting document by \(l\) and \(r\). In addition, after each occurrence of \(s\), after \(l\), and before \(r\), a \textit{space} is inserted. The documents are rendered horizontally if that fits the page. Otherwise they are aligned vertically. All seperators are put in front of the elements.

\[\text{hEncloseSep :: Doc \to Doc \to Doc \to [Doc] \to Doc}\]

The document \((\text{hEncloseSep} \, l \, r \, s \, xs)\) concatenates the documents \(xs\) seperated by \(s\) and encloses the resulting document by \(l\) and \(r\).

The documents are rendered horizontally.

\[\text{fillEncloseSep :: Doc \to Doc \to Doc \to [Doc] \to Doc}\]

The document \((\text{fillEncloseSep} \, l \, r \, s \, xs)\) concatenates the documents \(xs\) seperated by \(s\) and encloses the resulting document by \(l\) and \(r\).

The documents are rendered horizontally if that fits the page. Otherwise they are aligned vertically. All seperators are put in front of the elements.

\[\text{fillEncloseSepSpaced :: Doc \to Doc \to Doc \to [Doc] \to Doc}\]

The document \((\text{fillEncloseSepSpaced} \, l \, r \, s \, xs)\) concatenates the documents \(xs\) seperated by \(s\) and encloses the resulting document by \(l\) and \(r\). In addition, after each occurrence of \(s\), after \(l\), and before \(r\), a \textit{space} is inserted.

The documents are rendered horizontally if that fits the page. Otherwise, they are aligned vertically. All seperators are put in front of the elements.

\[\text{list :: [Doc] \to Doc}\]

The document \((\text{list} \, xs)\) comma seperates the documents \(xs\) and encloses them in square brackets. The documents are rendered horizontally if that fits the page. Otherwise they are aligned vertically. All comma seperators are put in front of the elements.

\[\text{listSpaced :: [Doc] \to Doc}\]

Spaced version of \textit{list}.

\[\text{set :: [Doc] \to Doc}\]

The document \((\text{set} \, xs)\) comma seperates the documents \(xs\) and encloses them in braces. The documents are rendered horizontally if that fits the page. Otherwise they are aligned vertically. All comma seperators are put in front of the elements.
setSpaced :: [Doc] → Doc

Spaced version of set

tupled :: [Doc] → Doc

The document (tupled xs) comma separates the documents xs and encloses them in parenthesis. The documents are rendered horizontally if that fits the page. Otherwise they are aligned vertically. All comma separators are put in front of the elements.

tupledSpaced :: [Doc] → Doc

Spaced version of tupled

semiBraces :: [Doc] → Doc

The document (semiBraces xs) separates the documents xs with semi colons and encloses them in braces. The documents are rendered horizontally if that fits the page. Otherwise they are aligned vertically. All semi colons are put in front of the elements.

semiBracesSpaced :: [Doc] → Doc

Spaced version of semiBraces

close :: Doc → Doc → Doc → Doc

The document (close l r x) encloses document x between documents l and r using (<>). close l r x = l <> x <> r

squotes :: Doc → Doc

Document (squotes x) encloses document x with single quotes "."

dquotes :: Doc → Doc

Document (dquotes x) encloses document x with double quotes.

bquotes :: Doc → Doc

Document (bquotes x) encloses document x with back quotes "".

parens :: Doc → Doc

Document (parens x) encloses document x in parenthesis, "(" and ")".

parensIf :: Bool → Doc → Doc

Document (parensIf x) encloses document x in parenthesis, "(" and ")", iff the condition is true.

angles :: Doc → Doc

Document (angles x) encloses document x in angles, "<" and ">".
braces :: Doc → Doc

Document (braces x) encloses document x in braces, "{" and "}".

brackets :: Doc → Doc

Document (brackets x) encloses document x in square brackets, "[" and "]".

char :: Char → Doc

The document (char c) contains the literal character c. The character should not be a newline (\n), the function line should be used for line breaks.

string :: String → Doc

The document (string s) concatenates all characters in s using line for newline characters and char for all other characters. It is used instead of text whenever the text contains newline characters.

int :: Int → Doc

The document (int i) shows the literal integer i using text.

float :: Float → Doc

The document (float f) shows the literal float f using text.

lparen :: Doc

The document lparen contains a left parenthesis, "(".

rparen :: Doc

The document rparen contains a right parenthesis, ")".

langle :: Doc

The document langle contains a left angle, "<".

rangle :: Doc

The document rangle contains a right angle, ">".

lbrace :: Doc

The document lbrace contains a left brace, "{".

rbrace :: Doc

The document rbrace contains a right brace, "}".

lbracket :: Doc

The document lbracket contains a left square bracket, "[".
rbracket :: Doc

The document rbracket contains a right square bracket, "]".
squote :: Doc

The document squote contains a single quote, "'".
dquote :: Doc

The document dquote contains a double quote.
semi :: Doc

The document semi contains a semi colon, ";".
colon :: Doc

The document colon contains a colon, ":".
comma :: Doc

The document comma contains a comma, ",".
space :: Doc

The document space contains a single space, " ".

\[x \leftrightarrow y = x \leftrightarrow \text{space} \leftrightarrow y\]
dot :: Doc

The document dot contains a single dot, ".".
backslash :: Doc

The document backslash contains a back slash, "\".
equals :: Doc

The document equals contains an equal sign, "+".
larrow :: Doc

The document larrow contains a left arrow sign, "<-".
rarrow :: Doc

The document rarrow contains a right arrow sign, "->".
doubleArrow :: Doc

The document doubleArrow contains an double arrow sign, "=>".
doubleColon :: Doc
The document `doubleColon` contains a double colon sign, "::".

```
bar :: Doc
```

The document `bar` contains a vertical bar sign, "|".

```
at :: Doc
```

The document `at` contains an at sign, "@".

```
tilde :: Doc
```

The document `tilde` contains a tilde sign, "~".

```
fill :: Int → Doc → Doc
```

The document `(fill i d)` renders document `d`. It than appends spaces until the width is equal to `i`. If the width of `d` is already larger, nothing is appended. This combinator is quite useful in practice to output a list of bindings. The following example demonstrates this.

```
types = ["empty","Doc")
        ,("nest","Int -> Doc -> Doc")
        ,("linebreak","Doc")]
```

```
ptype (name,tp)
    = fill 6 (text name) <+> text "::" <+> text tp
```

```
test = text "let" <+> align (vcat (map ptype types))
```

Which is layed out as:

```
let empty :: Doc
    nest :: Int -> Doc -> Doc
    linebreak :: Doc
```

Note that `fill` is not guaranteed to be linear-time bounded since it has to compute the width of a document before pretty printing it.

```
fillBreak :: Int → Doc → Doc
```

The document `(fillBreak i d)` first renders document `d`. It than appends spaces until the width is equal to `i`. If the width of `d` is already larger than `i`, the nesting level is increased by `i` and a line is appended. When we redefine `ptype` in the previous example to use `fillBreak`, we get a useful variation of the previous output:

```
ptype (name,tp)
    = fillBreak 6 (text name) <+> text "::" <+> text tp
```
The output will now be:

```haskell
let empty :: Doc
    nest :: Int -> Doc -> Doc
    linebreak :: Doc

Note that fillBreak is not guaranteed to be linear-time bounded since it has to compute
the width of a document before pretty printing it.

bold :: Doc -> Doc

The document (bold d) displays document d with bold text

faint :: Doc -> Doc

The document (faint d) displays document d with faint text

blinkSlow :: Doc -> Doc

The document (blinkSlow d) displays document d with slowly blinking text (rarely
supported)

blinkRapid :: Doc -> Doc

The document (blinkRapid d) displays document d with rapidly blinking text (rarely
supported)

italic :: Doc -> Doc

The document (italic d) displays document d with italicized text (rarely supported)

underline :: Doc -> Doc

The document (underline d) displays document d with underlined text

crossout :: Doc -> Doc

The document (crossout d) displays document d with crossed out text

inverse :: Doc -> Doc

The document (inverse d) displays document d with inversed coloring, i.e. use text
color of d as background color and background color of d as text color

black :: Doc -> Doc

The document (black d) displays document d with black text color

red :: Doc -> Doc

The document (red d) displays document d with red text color
```
green :: Doc \rightarrow Doc
    The document \((\text{green } d)\) displays document \(d\) with green text color

yellow :: Doc \rightarrow Doc
    The document \((\text{yellow } d)\) displays document \(d\) with yellow text color

blue :: Doc \rightarrow Doc
    The document \((\text{blue } d)\) displays document \(d\) with blue text color

magenta :: Doc \rightarrow Doc
    The document \((\text{magenta } d)\) displays document \(d\) with magenta text color

cyan :: Doc \rightarrow Doc
    The document \((\text{cyan } d)\) displays document \(d\) with cyan text color

white :: Doc \rightarrow Doc
    The document \((\text{white } d)\) displays document \(d\) with white text color

bgBlack :: Doc \rightarrow Doc
    The document \((\text{bgBlack } d)\) displays document \(d\) with black background color

bgRed :: Doc \rightarrow Doc
    The document \((\text{bgRed } d)\) displays document \(d\) with red background color

bgGreen :: Doc \rightarrow Doc
    The document \((\text{bgGreen } d)\) displays document \(d\) with green background color

bgYellow :: Doc \rightarrow Doc
    The document \((\text{bgYellow } d)\) displays document \(d\) with yellow background color

bgBlue :: Doc \rightarrow Doc
    The document \((\text{bgBlue } d)\) displays document \(d\) with blue background color

bgMagenta :: Doc \rightarrow Doc
    The document \((\text{bgMagenta } d)\) displays document \(d\) with magenta background color

bgCyan :: Doc \rightarrow Doc
    The document \((\text{bgCyan } d)\) displays document \(d\) with cyan background color

bgWhite :: Doc \rightarrow Doc
    The document \((\text{bgWhite } d)\) displays document \(d\) with white background color

pretty :: Int \rightarrow Doc \rightarrow String
    \((\text{pretty } w \ d)\) pretty prints document \(d\) with a page width of \(w\) characters
A.2.29 Library Profile

Preliminary library to support profiling.

Exported types:

data ProcessInfo

   The data type for representing information about the state of a Curry process.

Exported constructors:

• RunTime :: ProcessInfo
  RunTime
  – the run time in milliseconds

• ElapsedTime :: ProcessInfo
  ElapsedTime
  – the elapsed time in milliseconds

• Memory :: ProcessInfo
  Memory
  – the total memory in bytes

• Code :: ProcessInfo
  Code
  – the size of the code area in bytes

• Stack :: ProcessInfo
  Stack
  – the size of the local stack for recursive functions in bytes

• Heap :: ProcessInfo
  Heap
  – the size of the heap to store term structures in bytes

• Choices :: ProcessInfo
  Choices
  – the size of the choicepoint stack

• GarbageCollections :: ProcessInfo
  GarbageCollections
  – the number of garbage collections performed
Exported functions:

getProcessInfos :: IO [(ProcessInfo,Int)]

Returns various informations about the current state of the Curry process. Note that the returned values are implementation dependent so that one should interpret them with care!

Note for kics2 users: Since GHC version 7.x, one has to set the run-time option -T when this operation is used. This can be done by the kics2 command

:set rts -T

garbageCollectorOff :: IO ()

Turns off the garbage collector of the run-time system (if possible). This could be useful to get more precise data of memory usage.

garbageCollectorOn :: IO ()

Turns on the garbage collector of the run-time system (if possible).

garbageCollect :: IO ()

Invoke the garbage collector (if possible). This could be useful before run-time critical operations.

showMemInfo :: [(ProcessInfo,Int)] → String

Get a human readable version of the memory situation from the process infos.

printMemInfo :: IO ()

Print a human readable version of the current memory situation of the Curry process.

profileTime :: IO a → IO a

Print the time needed to execute a given IO action.

profileTimeNF :: a → IO ()

Evaluates the argument to normal form and print the time needed for this evaluation.

profileSpace :: IO a → IO a

Print the time and space needed to execute a given IO action. During the execution, the garbage collector is turned off to get the total space usage.

profileSpaceNF :: a → IO ()

Evaluates the argument to normal form and print the time and space needed for this evaluation. During the evaluation, the garbage collector is turned off to get the total space usage.
A.2.30 Library PropertyFile

A library to read and update files containing properties in the usual equational syntax, i.e., a property is defined by a line of the form prop=value where prop starts with a letter. All other lines (e.g., blank lines or lines starting with #) are considered as comment lines and are ignored.

Exported functions:

readPropertyFile :: String → IO [(String, String)]

Reads a property file and returns the list of properties. Returns empty list if the property file does not exist.

updatePropertyFile :: String → String → String → IO ()

Update a property in a property file or add it, if it is not already there.

A.2.31 Library Read

Library with some functions for reading special tokens.
This library is included for backward compatibility. You should use the library ReadNumeric which provides a better interface for these functions.

Exported functions:

readNat :: String → Int

Read a natural number in a string. The string might contain leadings blanks and the number is read up to the first non-digit.

readInt :: String → Int

Read a (possibly negative) integer in a string. The string might contain leadings blanks and the integer is read up to the first non-digit.

readHex :: String → Int

Read a hexadecimal number in a string. The string might contain leadings blanks and the integer is read up to the first non-hexadecimal digit.

A.2.32 Library ReadNumeric

Library with some functions for reading and converting numeric tokens.

Exported functions:

readInt :: String → Maybe (Int, String)

Read a (possibly negative) integer as a first token in a string. The string might contain leadings blanks and the integer is read up to the first non-digit. If the string does not start with an integer token, Nothing is returned, otherwise the result is Just (v, s), where v is the value of the integer and s is the remaining string without the integer token.
readNat :: String → Maybe (Int,String)

Read a natural number as a first token in a string. The string might contain leadings blanks and the number is read up to the first non-digit. If the string does not start with a natural number token, Nothing is returned, otherwise the result is Just (v, s) where v is the value of the number and s is the remaining string without the number token.

readHex :: String → Maybe (Int,String)

Read a hexadecimal number as a first token in a string. The string might contain leadings blanks and the number is read up to the first non-hexadecimal digit. If the string does not start with a hexadecimal number token, Nothing is returned, otherwise the result is Just (v, s) where v is the value of the number and s is the remaining string without the number token.

readOct :: String → Maybe (Int,String)

Read an octal number as a first token in a string. The string might contain leadings blanks and the number is read up to the first non-octal digit. If the string does not start with an octal number token, Nothing is returned, otherwise the result is Just (v, s) where v is the value of the number and s is the remaining string without the number token.

readBin :: String → Maybe (Int,String)

Read a binary number as a first token in a string. The string might contain leadings blanks and the number is read up to the first non-binary digit. If the string does not start with a binary number token, Nothing is returned, otherwise the result is Just (v, s) where v is the value of the number and s is the remaining string without the number token.

A.2.33 Library ReadShowTerm

Library for converting ground terms to strings and vice versa.

Exported functions:

showTerm :: a → String

Transforms a ground(!) term into a string representation in standard prefix notation. Thus, showTerm suspends until its argument is ground. This function is similar to the prelude function show but can read the string back with readUnqualifiedTerm (provided that the constructor names are unique without the module qualifier).

showQTerm :: a → String

Transforms a ground(!) term into a string representation in standard prefix notation. Thus, showQTerm suspends until its argument is ground. Note that this function differs from the prelude function show since it prefixes constructors with their module name in order to read them back with readQTerm.
readsUnqualifiedTerm :: [String] → String → [(a,String)]

Transform a string containing a term in standard prefix notation without module quali-
fiers into the corresponding data term. The first argument is a non-empty list of module
qualifiers that are tried to prefix the constructor in the string in order to get the qualified
constructors (that must be defined in the current program!). In case of a successful parse,
the result is a one element list containing a pair of the data term and the remaining
unparsed string.

readUnqualifiedTerm :: [String] → String → a

Transforms a string containing a term in standard prefix notation without module quali-
fiers into the corresponding data term. The first argument is a non-empty list of module
qualifiers that are tried to prefix the constructor in the string in order to get the qualified
constructors (that must be defined in the current program!).

Example: readUnqualifiedTerm ["Prelude"] "Just 3" evaluates to (Just 3)

readsTerm :: String → [(a,String)]

For backward compatibility. Should not be used since their use can be problematic in
case of constructors with identical names in different modules.

readTerm :: String → a

For backward compatibility. Should not be used since their use can be problematic in
case of constructors with identical names in different modules.

readsQTerm :: String → [(a,String)]

Transforms a string containing a term in standard prefix notation with qualified con-
structor names into the corresponding data term. In case of a successful parse, the result
is a one element list containing a pair of the data term and the remaining unparsed string.

readQTerm :: String → a

Transforms a string containing a term in standard prefix notation with qualified con-
structor names into the corresponding data term.

readQTermFile :: String → IO a

Reads a file containing a string representation of a term in standard prefix notation and
returns the corresponding data term.

readQTermListFile :: String → IO [a]

Reads a file containing lines with string representations of terms of the same type and
returns the corresponding list of data terms.

writeQTermFile :: String → a → IO ()

Writes a ground term into a file in standard prefix notation.

writeQTermListFile :: String → [a] → IO ()

Writes a list of ground terms into a file. Each term is written into a separate line which
might be useful to modify the file with a standard text editor.
A.2.34 Library SetFunctions

This module contains an implementation of set functions. The general idea of set functions is described in:

Intuition: If \( f \) is an \( n \)-ary function, then \((\text{setn} \ f)\) is a set-valued function that collects all non-determinism caused by \( f \) (but not the non-determinism caused by evaluating arguments!) in a set. Thus, \((\text{setn} \ f \ \text{a1} \ldots \ \text{an})\) returns the set of all values of \((f \ \text{b1} \ldots \ \text{bn})\) where \(\text{b1},\ldots,\text{bn}\) are values of the arguments \(\text{a1},\ldots,\text{an}\) (i.e., the arguments are evaluated "outside" this capsule so that the non-determinism caused by evaluating these arguments is not captured in this capsule but yields several results for \((\text{setn} \ldots)\). Similarly, logical variables occurring in \(\text{a1},\ldots,\text{an}\) are not bound inside this capsule.

The set of values returned by a set function is represented by an abstract type \texttt{Values} on which several operations are defined in this module. Actually, it is a multiset of values, i.e., duplicates are not removed.

The handling of failures and nested occurrences of set functions is not specified in the previous paper. Thus, a detailed description of the semantics of set functions as implemented in this library can be found in the paper

Exported types:

\begin{verbatim}
data Values =
  Abstract type representing multisets of values.
\end{verbatim}

Exported constructors:

Exported functions:

\begin{verbatim}
set0 :: a → Values a
  Combinator to transform a 0-ary function into a corresponding set function.

set0With :: (SearchTree a → ValueSequence a) → a → Values a
  Combinator to transform a 0-ary function into a corresponding set function that uses a given strategy to compute its values.

set1 :: (a → b) → a → Values b
  Combinator to transform a unary function into a corresponding set function.
\end{verbatim}
set1With :: (SearchTree a → ValueSequence a) → (b → a) → b → Values a

Combinator to transform a unary function into a corresponding set function that uses a given strategy to compute its values.

set2 :: (a → b → c) → a → b → Values c

Combinator to transform a binary function into a corresponding set function.

set2With :: (SearchTree a → ValueSequence a) → (b → c → a) → b → c → Values a

Combinator to transform a binary function into a corresponding set function that uses a given strategy to compute its values.

set3 :: (a → b → c → d) → a → b → c → Values d

Combinator to transform a function of arity 3 into a corresponding set function.

set3With :: (SearchTree a → ValueSequence a) → (b → c → d → a) → b → c → d → Values a

Combinator to transform a function of arity 3 into a corresponding set function that uses a given strategy to compute its values.

set4 :: (a → b → c → d → e) → a → b → c → d → Values e

Combinator to transform a function of arity 4 into a corresponding set function.

set4With :: (SearchTree a → ValueSequence a) → (b → c → d → e → a) → b → c → d → e → Values a

Combinator to transform a function of arity 4 into a corresponding set function that uses a given strategy to compute its values.

set5 :: (a → b → c → d → e → f) → a → b → c → d → e → Values f

Combinator to transform a function of arity 5 into a corresponding set function.

set5With :: (SearchTree a → ValueSequence a) → (b → c → d → e → f → a) → b → c → d → e → f → Values a

Combinator to transform a function of arity 5 into a corresponding set function that uses a given strategy to compute its values.

set6 :: (a → b → c → d → e → f → g) → a → b → c → d → e → f → Values g

Combinator to transform a function of arity 6 into a corresponding set function.

set6With :: (SearchTree a → ValueSequence a) → (b → c → d → e → f → g → a) → b → c → d → e → f → g → Values a
Combinator to transform a function of arity 6 into a corresponding set function that uses a given strategy to compute its values.

\[
\text{set7} :: (a \to b \to c \to d \to e \to f \to g \to h) \to a \to b \to c \to d \to e \to f \to g \to \text{Values } h
\]

Combinator to transform a function of arity 7 into a corresponding set function.

\[
\text{set7With} :: \text{SearchTree } a \to \text{ValueSequence } a \to (b \to c \to d \to e \to f \to g \to h \to a) \to b \to c \to d \to e \to f \to g \to h \to \text{Values } a
\]

Combinator to transform a function of arity 7 into a corresponding set function that uses a given strategy to compute its values.

\[
isEmpty :: \text{Values } a \to \text{Bool}
\]

Is a multiset of values empty?

\[
\text{notEmpty} :: \text{Values } a \to \text{Bool}
\]

Is a multiset of values not empty?

\[
\text{value0f} :: a \to \text{Values } a \to \text{Bool}
\]

Is some value an element of a multiset of values?

\[
\text{choose} :: \text{Values } a \to (a,\text{Values } a)
\]

Chooses (non-deterministically) some value in a multiset of values and returns the chosen value and the remaining multiset of values. Thus, if we consider the operation \text{chooseValue} by

\[
\text{chooseValue } x = \text{fst } (\text{choose } x)
\]

then \((\text{set1 } \text{chooseValue})\) is the identity on value sets, i.e., \((\text{set1 } \text{chooseValue } s)\) contains the same elements as the value set \(s\).

\[
\text{chooseValue} :: \text{Values } a \to a
\]

Chooses (non-deterministically) some value in a multiset of values and returns the chosen value. Thus, \((\text{set1 } \text{chooseValue})\) is the identity on value sets, i.e., \((\text{set1 } \text{chooseValue } s)\) contains the same elements as the value set \(s\).

\[
\text{select} :: \text{Values } a \to (a,\text{Values } a)
\]

Selects (indeterministically) some value in a multiset of values and returns the selected value and the remaining multiset of values. Thus, \text{select} has always at most one value. It fails if the value set is empty.

**NOTE:** The usage of this operation is only safe (i.e., does not destroy completeness) if all values in the argument set are identical.
selectValue :: Values a → a

Selects (indeterministically) some value in a multiset of values and returns the selected value. Thus, selectValue has always at most one value. It fails if the value set is empty.

NOTE: The usage of this operation is only safe (i.e., does not destroy completeness) if all values in the argument set are identical.

mapValues :: (a → b) → Values a → Values b

Maps a function to all elements of a multiset of values.

foldValues :: (a → a → a) → a → Values a → a

Accumulates all elements of a multiset of values by applying a binary operation. This is similarly to fold on lists, but the binary operation must be commutative so that the result is independent of the order of applying this operation to all elements in the multiset.

filterValues :: (a → Bool) → Values a → Values a

Keeps all elements of a multiset of values that satisfy a predicate.

minValue :: (a → a → Bool) → Values a → a

Returns the minimal element of a non-empty multiset of values with respect to a given total ordering on the elements.

maxValue :: (a → a → Bool) → Values a → a

Returns the maximal element of a non-empty multiset of value with respect to a given total ordering on the elements.

values2list :: Values a → IO [a]

Puts all elements of a multiset of values in a list. Since the order of the elements in the list might depend on the time of the computation, this operation is an I/O action.

printValues :: Values a → IO ()

Prints all elements of a multiset of values.

sortValues :: Values a → [a]

Transforms a multiset of values into a list sorted by the standard term ordering. As a consequence, the multiset of values is completely evaluated.

sortValuesBy :: (a → a → Bool) → Values a → [a]

Transforms a multiset of values into a list sorted by a given ordering on the values. As a consequence, the multiset of values is completely evaluated. In order to ensure that the result of this operation is independent of the evaluation order, the given ordering must be a total order.
A.2.35 Library Socket

Library to support network programming with sockets. In standard applications, the server side uses the operations `listenOn` and `socketAccept` to provide some service on a socket, and the client side uses the operation `connectToSocket` to request a service.

Exported types:

```haskell
data Socket

    The abstract type of sockets.
```

Exported constructors:

Exported functions:

`listenOn :: Int → IO Socket`

Creates a server side socket bound to a given port number.

`listenOnFresh :: IO (Int,Socket)`

Creates a server side socket bound to a free port. The port number and the socket is returned.

`socketAccept :: Socket → IO (String,Handle)`

Returns a connection of a client to a socket. The connection is returned as a pair consisting of a string identifying the client (the format of this string is implementation-dependent) and a handle to a stream communication with the client. The handle is both readable and writable.

`waitForSocketAccept :: Socket → Int → IO (Maybe (String,Handle))`

Waits until a connection of a client to a socket is available. If no connection is available within the time limit, it returns Nothing, otherwise the connection is returned as a pair consisting of a string identifying the client (the format of this string is implementation-dependent) and a handle to a stream communication with the client.

`sClose :: Socket → IO ()`

Closes a server socket.

`connectToSocket :: String → Int → IO Handle`

Creates a new connection to a Unix socket.

A.2.36 Library State

This library provides an implementation of the state monad.
Exported types:

type State a b = a → (b,a)

Exported functions:

bindS :: (a → (b,a)) → (b → a → (c,a)) → a → (c,a)

bindS_ :: (a → (b,a)) → (a → (c,a)) → a → (c,a)

returnS :: a → b → (a,b)

getS :: a → (a,a)

putS :: a → a → ((),a)

modifyS :: (a → a) → a → ((),a)

sequenceS :: [a → (b,a)] → a → ([b],a)

sequenceS_ :: [a → (b,a)] → a → ((),a)

mapS :: (a → b → (c,b)) → [a] → b → ([c],b)

mapS_ :: (a → b → (c,b)) → [a] → b → ((),b)

runState :: (a → (b,a)) → a → (b,a)

evalState :: (a → (b,a)) → a → b

execState :: (a → (b,a)) → a → a

liftS :: (a → b) → (c → (a,c)) → c → (b,c)

liftS2 :: (a → b → c) → (d → (a,d)) → (d → (b,d)) → d → (c,d)
A.2.37 Library System

Library to access parts of the system environment.

Exported functions:

getCPUCputTime :: IO Int

Returns the current cpu time of the process in milliseconds.

getElapsedTime :: IO Int

Returns the current elapsed time of the process in milliseconds. This operation is not supported in KiCS2 (there it always returns 0), but only included for compatibility reasons.

getArgs :: IO [String]

Returns the list of the program’s command line arguments. The program name is not included.

getEnviron :: String → IO String

Returns the value of an environment variable. The empty string is returned for undefined environment variables.

setEnviron :: String → String → IO ()

Set an environment variable to a value. The new value will be passed to subsequent shell commands (see system) and visible to subsequent calls to getEnviron (but it is not visible in the environment of the process that started the program execution).

unsetEnviron :: String → IO ()

Removes an environment variable that has been set by setEnviron.

getHostname :: IO String

Returns the hostname of the machine running this process.

getPID :: IO Int

Returns the process identifier of the current Curry process.

getProgName :: IO String

Returns the name of the current program, i.e., the name of the main module currently executed.

system :: String → IO Int

Executes a shell command and return with the exit code of the command. An exit status of zero means successful execution.
exitWith :: Int → IO a

Terminates the execution of the current Curry program and returns the exit code given by the argument. An exit code of zero means successful execution.

sleep :: Int → IO ()

The evaluation of the action (sleep n) puts the Curry process asleep for n seconds.

isPosix :: Bool

Is the underlying operating system a POSIX system (unix, MacOS)?

isWindows :: Bool

Is the underlying operating system a Windows system?

A.2.38 Library Time

Library for handling date and time information.

Exported types:

data ClockTime

    ClockTime represents a clock time in some internal representation.

Exported constructors:

data CalendarTime

    A calendar time is presented in the following form: (CalendarTime year month day hour minute second timezone) where timezone is an integer representing the timezone as a difference to UTC time in seconds.

Exported constructors:

- CalendarTime :: Int → Int → Int → Int → Int → Int → Int → CalendarTime

Exported functions:

ctYear :: CalendarTime → Int

    The year of a calendar time.

ctMonth :: CalendarTime → Int

    The month of a calendar time.

ctDay :: CalendarTime → Int

    The day of a calendar time.
ctHour :: CalendarTime → Int

The hour of a calendar time.

ctMin :: CalendarTime → Int

The minute of a calendar time.

ctSec :: CalendarTime → Int

The second of a calendar time.

ctTZ :: CalendarTime → Int

The time zone of a calendar time. The value of the time zone is the difference to UTC time in seconds.

getClockTime :: IO ClockTime

Returns the current clock time.

getLocalTime :: IO CalendarTime

Returns the local calendar time.

clockTimeToInt :: ClockTime → Int

Transforms a clock time into a unique integer. It is ensured that clock times that differ in at least one second are mapped into different integers.

toCalendarTime :: ClockTime → IO CalendarTime

Transforms a clock time into a calendar time according to the local time (if possible). Since the result depends on the local environment, it is an I/O operation.

toUTCTime :: ClockTime → CalendarTime

Transforms a clock time into a standard UTC calendar time. Thus, this operation is independent on the local time.

toClockTime :: CalendarTime → ClockTime

Transforms a calendar time (interpreted as UTC time) into a clock time.

calendarTimeToString :: CalendarTime → String

Transforms a calendar time into a readable form.

toDayString :: CalendarTime → String

Transforms a calendar time into a string containing the day, e.g., "September 23, 2006".

toTimeString :: CalendarTime → String

Transforms a calendar time into a string containing the time.
addSeconds :: Int → ClockTime → ClockTime
    Adds seconds to a given time.
addMinutes :: Int → ClockTime → ClockTime
    Adds minutes to a given time.
addHours :: Int → ClockTime → ClockTime
    Adds hours to a given time.
addDays :: Int → ClockTime → ClockTime
    Adds days to a given time.
addMonths :: Int → ClockTime → ClockTime
    Adds months to a given time.
addYears :: Int → ClockTime → ClockTime
    Adds years to a given time.
daysOfMonth :: Int → Int → Int
    Gets the days of a month in a year.
validDate :: Int → Int → Int → Bool
    Is a date consisting of year/month/day valid?
compareDate :: CalendarTime → CalendarTime → Ordering
    Compares two dates (don’t use it, just for backward compatibility!).
compareCalendarTime :: CalendarTime → CalendarTime → Ordering
    Compares two calendar times.
compareClockTime :: ClockTime → ClockTime → Ordering
    Compares two clock times.

A.2.39 Library Unsafe

Library containing unsafe operations. These operations should be carefully used (e.g., for testing or debugging). These operations should not be used in application programs!

Exported functions:

unsafePerformIO :: IO a → a
    Performs and hides an I/O action in a computation (use with care!).
trace :: String → a → a
    Prints the first argument as a side effect and behaves as identity on the second argument.
A.2.40 Library Test.EasyCheck

EasyCheck is a library for automated, property-based testing of Curry programs. The ideas behind EasyCheck are described in this paper. The CurryCheck tool automatically executes tests defined with this library. CurryCheck supports the definition of unit tests (also for I/O operations) and property tests parameterized over some arguments. CurryCheck is described in more detail in this paper.

Note that this module defines the interface of EasyCheck to define properties. The operations to actually execute the tests are contained in the accompanying library Test.EasyCheckExec.

Exported types:

data PropIO

    Abstract type to represent properties involving IO actions.

    * Exported constructors:

    data Test

    Abstract type to represent a single test for a property to be checked. A test consists of the result computed for this test, the arguments used for this test, and the labels possibly assigned to this test by annotating properties.

    * Exported constructors:

    data Result

    Data type to represent the result of checking a property.

    * Exported constructors:

      • undef :: Result
      • ok :: Result
      • Falsified :: [String] → Result
      • Ambigious :: [Bool] → [String] → Result

    data Prop

    Abstract type to represent properties to be checked. Basically, it contains all tests to be executed to check the property.

    * Exported constructors:
Exported functions:

\[ \text{returns} :: \text{IO } a \to a \to \text{PropIO} \]

The property \[ \text{returns } a \times \text{x} \] is satisfied if the execution of the I/O action \[ a \] returns the value \[ x \].

\[ \text{sameReturns} :: \text{IO } a \to \text{IO } a \to \text{PropIO} \]

The property \[ \text{sameReturns } a_1 \text{ a}_2 \] is satisfied if the execution of the I/O actions \[ a_1 \text{ and } a_2 \] return identical values.

\[ \text{toError} :: a \to \text{PropIO} \]

The property \[ \text{toError } a \] is satisfied if the evaluation of the argument to normal form yields an exception.

\[ \text{toIOError} :: \text{IO } a \to \text{PropIO} \]

The property \[ \text{toIOError } a \] is satisfied if the execution of the I/O action \[ a \] causes an exception.

\[ \text{ioTestOf} :: \text{PropIO } \to \text{Bool } \to \text{String } \to \text{IO } (\text{Maybe } \text{String}) \]

Extracts the tests of an I/O property (used by the test runner).

\[ \text{testsOf} :: \text{Prop } \to \text{[Test]} \]

Extracts the tests of a property (used by the test runner).

\[ \text{result} :: \text{Test } \to \text{Result} \]

Extracts the result of a test.

\[ \text{args} :: \text{Test } \to \text{[String]} \]

Extracts the arguments of a test.

\[ \text{stamp} :: \text{Test } \to \text{[String]} \]

Extracts the labels of a test.

\[ \text{updArgs} :: (\text{[String]} \to \text{[String]}) \to \text{Test } \to \text{Test} \]

Updates the arguments of a test.

\[ \text{test} :: a \to (\text{[a]} \to \text{Bool}) \to \text{Prop} \]

Constructs a property to be tested from an arbitrary expression (first argument) and a predicate that is applied to the list of non-deterministic values. The given predicate determines whether the constructed property is satisfied or falsified for the given expression.

\[ (-=-) :: a \to a \to \text{Prop} \]
The property $x \xleftarrow{x} y$ is satisfied if $x$ and $y$ have deterministic values that are equal.

$(\ll{\sim}) :: a \to a \to \text{Prop}$

The property $x \ll{\sim} y$ is satisfied if the sets of the values of $x$ and $y$ are equal.

$(\gg) :: a \to a \to \text{Prop}$

The property $x \gg y$ is satisfied if $x$ evaluates to every value of $y$. Thus, the set of values of $y$ must be a subset of the set of values of $x$.

$(\ll{\sim}) :: a \to a \to \text{Prop}$

The property $x \ll{\sim} y$ is satisfied if $y$ evaluates to every value of $x$. Thus, the set of values of $x$ must be a subset of the set of values of $y$.

$(\ll{\sim}{\sim}) :: a \to a \to \text{Prop}$

The property $x \ll{\sim}{\sim} y$ is satisfied if the multisets of the values of $x$ and $y$ are equal.

$(\Rightarrow{\Rightarrow}) :: \text{Bool} \to \text{Prop} \to \text{Prop}$

A conditional property is tested if the condition evaluates to True.

$solutionOf :: (a \to \text{Bool}) \to a$

$solutionOf p$ returns (non-deterministically) a solution of predicate $p$. This operation is useful to test solutions of predicates.

$\text{is} :: a \to (a \to \text{Bool}) \to \text{Prop}$

The property $\text{is} x p$ is satisfied if $x$ has a deterministic value which satisfies $p$.

$\text{isAlways} :: a \to (a \to \text{Bool}) \to \text{Prop}$

The property $\text{isAlways} x p$ is satisfied if all values of $x$ satisfy $p$.

$\text{isEventually} :: a \to (a \to \text{Bool}) \to \text{Prop}$

The property $\text{isEventually} x p$ is satisfied if some value of $x$ satisfies $p$.

$\text{uniquely} :: \text{Bool} \to \text{Prop}$

The property $\text{uniquely} x$ is satisfied if $x$ has a deterministic value which is true.

$\text{always} :: \text{Bool} \to \text{Prop}$

The property $\text{always} x$ is satisfied if all values of $x$ are true.

$\text{eventually} :: \text{Bool} \to \text{Prop}$

The property $\text{eventually} x$ is satisfied if some value of $x$ is true.

$failing :: a \to \text{Prop}$
The property **failing** \( x \) is satisfied if \( x \) has no value.

**successful :: a \to Prop**

The property **successful** \( x \) is satisfied if \( x \) has at least one value.

**deterministic :: a \to Prop**

The property **deterministic** \( x \) is satisfied if \( x \) has exactly one value.

**(#) :: a \to Int \to Prop**

The property \( x \# n \) is satisfied if \( x \) has \( n \) values.

**(#<) :: a \to Int \to Prop**

The property \( x \#< n \) is satisfied if \( x \) has less than \( n \) values.

**(#>) :: a \to Int \to Prop**

The property \( x \#> n \) is satisfied if \( x \) has more than \( n \) values.

**for :: a \to (a \to Prop) \to Prop**

The property **for** \( x \) \( p \) is satisfied if all values \( y \) of \( x \) satisfy property \( p \ y \).

**forAll :: [a] \to (a \to Prop) \to Prop**

The property **forAll** \( xs \) \( p \) is satisfied if all values \( x \) of the list \( xs \) satisfy property \( p \ x \).

**forAllValues :: (a \to Prop) \to [b] \to (b \to a) \to Prop**

Only for internal use by the test runner.

**(<=>) :: a \to a \to Prop**

The property \( f \<::> g \) is satisfied if \( f \) and \( g \) are equivalent operations, i.e., they can be replaced in any context without changing the computed results.

**label :: String \to Prop \to Prop**

Assign a label to a property. All labeled tests are counted and shown at the end.

**classify :: Bool \to String \to Prop \to Prop**

Assign a label to a property if the first argument is \( True \). All labeled tests are counted and shown at the end. Hence, this combinator can be used to classify tests:

\[
\text{multIsComm } x \ y = \text{classify } (x<0 \ || \ y<0) \ "Negative" \ $ x*y \ -=- y*x
\]

**trivial :: Bool \to Prop \to Prop**

Assign the label "trivial" to a property if the first argument is \( True \). All labeled tests are counted and shown at the end.
collect :: a → Prop → Prop

Assign a label showing the given argument to a property. All labeled tests are counted and shown at the end.

collectAs :: String → a → Prop → Prop

Assign a label showing a given name and the given argument to a property. All labeled tests are counted and shown at the end.

valuesOfSearchTree ::SearchTree a → [a]

Extracts values of a search tree according to a given strategy (here: randomized diagonalization of levels with flattening).

valuesOf :: a → [a]

Computes the list of all values of the given argument according to a given strategy (here: randomized diagonalization of levels with flattening).

A.2.41 Library Test.Prop

This module defines the interface of properties that can be checked with the CurryCheck tool, an automatic property-based test tool based on the EasyCheck library. The ideas behind EasyCheck are described in this paper. CurryCheck automatically tests properties defined with this library. CurryCheck supports the definition of unit tests (also for I/O operations) and property tests parameterized over some arguments. CurryCheck is described in more detail in this paper. Basically, this module is a stub clone of the EasyCheck library which contains only the interface of the operations used to specify properties. Hence, this library does not import any other library. This supports the definition of properties in any other module (except for the prelude).

Exported types:

data PropIO

Abstract type to represent properties involving IO actions.

Exported constructors:

data Prop

Abstract type to represent properties to be checked. Basically, it contains all tests to be executed to check the property.

Exported constructors:
Exported functions:

```
returns :: IO a → a → PropIO

The property returns a x is satisfied if the execution of the I/O action a returns the
value x.

sameReturns :: IO a → IO a → PropIO

The property sameReturns a1 a2 is satisfied if the execution of the I/O actions a1 and
a2 return identical values.

toError :: a → PropIO

The property toError a is satisfied if the evaluation of the argument to normal form
yields an exception.

toIOError :: IO a → PropIO

The property toIOError a is satisfied if the execution of the I/O action a causes an
exception.

(<=-) :: a → a → Prop

The property x <=- y is satisfied if x and y have deterministic values that are equal.

(<~>) :: a → a → Prop

The property x <~> y is satisfied if the sets of the values of x and y are equal.

(">`) :: a → a → Prop

The property x ~> y is satisfied if x evaluates to every value of y. Thus, the set of
values of y must be a subset of the set of values of x.

(<~) :: a → a → Prop

The property x <~ y is satisfied if y evaluates to every value of x. Thus, the set of
values of x must be a subset of the set of values of y.

(<~~>) :: a → a → Prop

The property x <~~ y is satisfied if the multisets of the values of x and y are equal.

(==>) :: Bool → Prop → Prop

A conditional property is tested if the condition evaluates to True.

solutionOf :: (a → Bool) → a

solutionOf p returns (non-deterministically) a solution of predicate p. This operation
is useful to test solutions of predicates.

is :: a → (a → Bool) → Prop
```
The property is \( x \ p \) is satisfied if \( x \) has a deterministic value which satisfies \( p \).

\[
isAlways :: a \to (a \to \text{Bool}) \to \text{Prop}
\]

The property \( \text{isAlways} \ x \ p \) is satisfied if all values of \( x \) satisfy \( p \).

\[
isEventually :: a \to (a \to \text{Bool}) \to \text{Prop}
\]

The property \( \text{isEventually} \ x \ p \) is satisfied if some value of \( x \) satisfies \( p \).

\[
\text{uniquely} :: \text{Bool} \to \text{Prop}
\]

The property \( \text{uniquely} \ x \) is satisfied if \( x \) has a deterministic value which is true.

\[
\text{always} :: \text{Bool} \to \text{Prop}
\]

The property \( \text{always} \ x \) is satisfied if all values of \( x \) are true.

\[
\text{eventually} :: \text{Bool} \to \text{Prop}
\]

The property \( \text{eventually} \ x \) is satisfied if some value of \( x \) is true.

\[
\text{failing} :: a \to \text{Prop}
\]

The property \( \text{failing} \ x \) is satisfied if \( x \) has no value.

\[
\text{successful} :: a \to \text{Prop}
\]

The property \( \text{successful} \ x \) is satisfied if \( x \) has at least one value.

\[
\text{deterministic} :: a \to \text{Prop}
\]

The property \( \text{deterministic} \ x \) is satisfied if \( x \) has exactly one value.

\[
(\#) :: a \to \text{Int} \to \text{Prop}
\]

The property \( x \ # \ n \) is satisfied if \( x \) has \( n \) values.

\[
(\#<) :: a \to \text{Int} \to \text{Prop}
\]

The property \( x \ #< \ n \) is satisfied if \( x \) has less than \( n \) values.

\[
(\#>) :: a \to \text{Int} \to \text{Prop}
\]

The property \( x \ #> \ n \) is satisfied if \( x \) has more than \( n \) values.

\[
\text{for} :: a \to (a \to \text{Prop}) \to \text{Prop}
\]

The property \( \text{for} \ x \ p \) is satisfied if all values \( y \) of \( x \) satisfy property \( p \ y \).

\[
\text{forAll} :: [a] \to (a \to \text{Prop}) \to \text{Prop}
\]

The property \( \text{forAll} \ xs \ p \) is satisfied if all values \( x \) of the list \( xs \) satisfy property \( p \ x \).

\[
(\leqslant\geqslant) :: a \to a \to \text{Prop}
\]

160
The property $f \iff g$ is satisfied if $f$ and $g$ are equivalent operations, i.e., they can be replaced in any context without changing the computed results.

**label :: String $\rightarrow$ Prop $\rightarrow$ Prop**

Assign a label to a property. All labeled tests are counted and shown at the end.

**classify :: Bool $\rightarrow$ String $\rightarrow$ Prop $\rightarrow$ Prop**

Assign a label to a property if the first argument is True. All labeled tests are counted and shown at the end. Hence, this combinator can be used to classify tests:

```
multIsComm x y = classify (x<0 || y<0) "Negative" $ x*y -=- y*x
```

**trivial :: Bool $\rightarrow$ Prop $\rightarrow$ Prop**

Assign the label "trivial" to a property if the first argument is True. All labeled tests are counted and shown at the end.

**collect :: a $\rightarrow$ Prop $\rightarrow$ Prop**

Assign a label showing the given argument to a property. All labeled tests are counted and shown at the end.

**collectAs :: String $\rightarrow$ a $\rightarrow$ Prop $\rightarrow$ Prop**

Assign a label showing a given name and the given argument to a property. All labeled tests are counted and shown at the end.

**valuesOf :: a $\rightarrow$ [a]**

Computes the list of all values of the given argument according to a given strategy (here: randomized diagonalization of levels with flattening).

### A.3 Data Structures and Algorithms

#### A.3.1 Library Array

Implementation of Arrays with Braun Trees. Conceptually, Braun trees are always infinite. Consequently, there is no test on emptiness.

**Exported types:**

data Array

**Exported constructors:**
Exported functions:

emptyErrorArray :: Array a

Creates an empty array which generates errors for non-initialized indexes.

emptyDefaultArray :: (Int → a) → Array a

Creates an empty array, call given function for non-initialized indexes.

NullOrDefault :: Array a → [(Int,a)] → Array a

Inserts a list of entries into an array.

update :: Array a → Int → a → Array a

Inserts a new entry into an array.

applyAt :: Array a → Int → (a → a) → Array a

Applies a function to an element.

(!) :: Array a → Int → a

Yields the value at a given position.

listToDefaultArray :: (Int → a) → [a] → Array a

Creates a default array from a list of entries.

listToErrorArray :: [a] → Array a

Creates an error array from a list of entries.

combine :: (a → b → c) → Array a → Array b → Array c

combine two arbitrary arrays

combineSimilar :: (a → a → a) → Array a → Array a → Array a

the combination of two arrays with identical default function and a combinator which is neutral in the default can be implemented much more efficient

A.3.2 Library Dequeue

An implementation of double-ended queues supporting access at both ends in constant amortized time.

Exported types:

data Queue

The datatype of a queue.

Exported constructors:
Exported functions:

`empty :: Queue a`

The empty queue.

`cons :: a → Queue a → Queue a`

Inserts an element at the front of the queue.

`snoc :: a → Queue a → Queue a`

Inserts an element at the end of the queue.

`isEmpty :: Queue a → Bool`

Is the queue empty?

`deqLength :: Queue a → Int`

Returns the number of elements in the queue.

`deqHead :: Queue a → a`

The first element of the queue.

`deqTail :: Queue a → Queue a`

Removes an element at the front of the queue.

`deqLast :: Queue a → a`

The last element of the queue.

`deqInit :: Queue a → Queue a`

Removes an element at the end of the queue.

`deqReverse :: Queue a → Queue a`

Reverses a double ended queue.

`rotate :: Queue a → Queue a`

Moves the first element to the end of the queue.

`matchHead :: Queue a → Maybe (a,Queue a)`

Matches the front of a queue. `matchHead q` is equivalent to `if isEmpty q then Nothing else Just (deqHead q, deqTail q)` but more efficient.

`matchLast :: Queue a → Maybe (a,Queue a)`

Matches the end of a queue. `matchLast q` is equivalent to `if isEmpty q then Nothing else Just (deqLast q, deqInit q)` but more efficient.

`listToDeq :: [a] → Queue a`

Transforms a list to a double ended queue.

`deqToList :: Queue a → [a]`

Transforms a double ended queue to a list.
A.3.3 Library FiniteMap

A finite map is an efficient purely functional data structure to store a mapping from keys to values. In order to store the mapping efficiently, an irreflexive(!) order predicate has to be given, i.e., the order predicate \( \text{le} \) should not satisfy \( (\text{le} x x) \) for some key \( x \).

Example: To store a mapping from \( \text{Int} \rightarrow \text{String} \), the finite map needs a Boolean predicate like \( (<) \). This version was ported from a corresponding Haskell library

**Exported types:**

```data FM```

**Exported constructors:**

**Exported functions:**

- `emptyFM :: (a → a → Bool) → FM a b`
  
  The empty finite map.

- `unitFM :: (a → a → Bool) → a → b → FM a b`
  
  Construct a finite map with only a single element.

- `listToFM :: (a → a → Bool) → [(a,b)] → FM a b`
  
  Builds a finite map from given list of tuples (key,element). For multiple occurences of key, the last corresponding element of the list is taken.

- `addToFM :: FM a b → a → b → FM a b`
  
  Throws away any previous binding and stores the new one given.

- `addListToFM :: FM a b → [(b,a)] → FM a b`
  
  Throws away any previous bindings and stores the new ones given. The items are added starting with the first one in the list

- `addToFM_C :: (a → a → a) → FM b a → b → a → FM b a`
  
  Instead of throwing away the old binding, `addToFM_C` combines the new element with the old one.

- `addListToFM_C :: (a → a → a) → FM b a → [(b,a)] → FM b a`
  
  Combine with a list of tuples (key,element), cf. `addToFM_C`

- `delFromFM :: FM a b → a → FM a b`
  
  Deletes key from finite map. Deletion doesn’t complain if you try to delete something which isn’t there
delListFromFM :: FM a b → [a] → FM a b
   Deletes a list of keys from finite map. Deletion doesn’t complain if you try to delete something which isn’t there

updFM :: FM a b → a → (b → b) → FM a b
   Applies a function to element bound to given key.

splitFM :: FM a b → a → Maybe (FM a b,(a,b))
   Combines delFrom and lookup.

plusFM :: FM a b → FM a b → FM a b
   Efficiently add key/element mappings of two maps into a single one. Bindings in right argument shadow those in the left

plusFM_C :: (a → a → a) → FM b a → FM b a → FM b a
   Efficiently combine key/element mappings of two maps into a single one, cf. addToFM_C

minusFM :: FM a b → FM a b → FM a b
   (minusFM a1 a2) deletes from a1 any bindings which are bound in a2

intersectFM :: FM a b → FM a b → FM a b
   Filters only those keys that are bound in both of the given maps. The elements will be taken from the second map.

intersectFM_C :: (a → b → c) → FM d a → FM d b → FM d c
   Filters only those keys that are bound in both of the given maps and combines the elements as in addToFM_C.

foldFM :: (a → b → c → c) → c → FM a b → c
   Folds finite map by given function.

mapFM :: (a → b → c) → FM a b → FM a c
   Applies a given function on every element in the map.

filterFM :: (a → b → Bool) → FM a b → FM a b
   Yields a new finite map with only those key/element pairs matching the given predicate.

sizeFM :: FM a b → Int
   How many elements does given map contain?

eqFM :: FM a b → FM a b → Bool
Do two given maps contain the same key/element pairs?

isEmptFM :: FM a b → Bool

Is the given finite map empty?

elemFM :: a → FM a b → Bool

Does given map contain given key?

lookupFM :: FM a b → a → Maybe b

Retrieves element bound to given key

lookupWithDefaultFM :: FM a b → b → a → b

Retrieves element bound to given key. If the element is not contained in map, return
default value.

keyOrder :: FM a b → a → a → Bool

Retrieves the ordering on which the given finite map is built.

minFM :: FM a b → Maybe (a,b)

Retrieves the smallest key/element pair in the finite map according to the basic key
ordering.

maxFM :: FM a b → Maybe (a,b)

Retrieves the greatest key/element pair in the finite map according to the basic key
ordering.

fmToList :: FM a b → [(a,b)]

Builds a list of key/element pairs. The list is ordered by the initially given irreflexive
order predicate on keys.

keysFM :: FM a b → [a]

Retrieves a list of keys contained in finite map. The list is ordered by the initially given
irreflexive order predicate on keys.

eltsFM :: FM a b → [b]

Retrieves a list of elements contained in finite map. The list is ordered by the initially given
irreflexive order predicate on keys.

fmToListPreOrder :: FM a b → [(a,b)]

Retrieves list of key/element pairs in preorder of the internal tree. Useful for lists that
will be retransformed into a tree or to match any elements regardless of basic order.

fmSortBy :: (a → a → Bool) → [a] → [a]
Sorts a given list by inserting and retrieving from finite map. Duplicates are deleted.

\[\text{showFM} :: \text{FM} \ a \ b \rightarrow \text{String}\]

Transforms a finite map into a string. For efficiency reasons, the tree structure is shown which is valid for reading only if one uses the same ordering predicate.

\[\text{readFM} :: (a \rightarrow a \rightarrow \text{Bool}) \rightarrow \text{String} \rightarrow \text{FM} \ a \ b\]

Transforms a string representation of a finite map into a finite map. One has two provide the same ordering predicate as used in the original finite map.

### A.3.4 Library Random

Library for pseudo-random number generation in Curry.

This library provides operations for generating pseudo-random number sequences. For any given seed, the sequences generated by the operations in this module should be identical to the sequences generated by the java.util.Random package.

The algorithm is taken from [http://en.wikipedia.org/wiki/Random_number_generation](http://en.wikipedia.org/wiki/Random_number_generation). There is an assumption that all operations are implicitly executed mod 2\(^32\) (unsigned 32-bit integers) !!!

GHC computes between -2\(^{32}\) and 2\(^{32}-1\), thus the sequence is NOT as random as one would like.

```haskell
m_w = <choose-initializer>; /* must not be zero */
m_z = <choose-initializer>; /* must not be zero */

uint get_random()
{
    m_z = 36969 * (m_z & 65535) + (m_z >> 16);
m_w = 18000 * (m_w & 65535) + (m_w >> 16);
    return (m_z << 16) + m_w; /* 32-bit result */
}
```

Exported functions:

\[\text{nextInt} :: \text{Int} \rightarrow \text{[Int]}\]

Returns a sequence of pseudorandom, integer values.

\[\text{nextIntRange} :: \text{Int} \rightarrow \text{Int} \rightarrow \text{[Int]}\]

Returns a pseudorandom sequence of values between 0 (inclusive) and the specified value (exclusive).

\[\text{nextBoolean} :: \text{Int} \rightarrow \text{[Bool]}\]

Returns a pseudorandom sequence of boolean values.

\[\text{getRandomSeed} :: \text{IO} \ \text{Int}\]

167
Returns a time-dependent integer number as a seed for really random numbers. Should only be used as a seed for pseudorandom number sequence and not as a random number since the precision is limited to milliseconds

\text{shuffle} :: \text{Int} \rightarrow [a] \rightarrow [a]

Computes a random permutation of the given list.

### A.3.5 Library RedBlackTree

Library with an implementation of red-black trees:

Serves as the base for both TableRBT and SetRBT. All the operations on trees are generic, i.e., one has to provide two explicit order predicates ("lessThan" and "eq"below) on elements.

#### Exported types:

**data RedBlackTree**

A red-black tree consists of a tree structure and three order predicates. These predicates generalize the red black tree. They define 1) equality when inserting into the tree
e.g. for a set eqInsert is (==), for a multiset it is (-> False) for a lookUp-table it is ((==) . fst) 2) equality for looking up values e.g. for a set eqLookUp is (==), for a multiset it is (==) for a lookUp-table it is ((==) . fst) 3) the (less than) relation for the binary search tree

**Exported constructors:**

- empty :: (a \rightarrow a \rightarrow \text{Bool}) \rightarrow (a \rightarrow a \rightarrow \text{Bool}) \rightarrow (a \rightarrow a \rightarrow \text{Bool}) \rightarrow \text{RedBlackTree} a

The three relations are inserted into the structure by function empty. Returns an empty tree, i.e., an empty red-black tree augmented with the order predicates.

- isEmpty :: \text{RedBlackTree} a \rightarrow \text{Bool}

Test on emptiness

- newTreeLike :: \text{RedBlackTree} a \rightarrow \text{RedBlackTree} a

Creates a new empty red black tree from with the same ordering as a give one.

- lookup :: a \rightarrow \text{RedBlackTree} a \rightarrow \text{Maybe} a

Returns an element if it is contained in a red-black tree.

- update :: a \rightarrow \text{RedBlackTree} a \rightarrow \text{RedBlackTree} a

Updates/inserts an element into a RedBlackTree.
delete :: a → RedBlackTree a → RedBlackTree a

Deletes entry from red black tree.

tree2list :: RedBlackTree a → [a]

Transforms a red-black tree into an ordered list of its elements.

sortBy :: (a → a → Bool) → [a] → [a]

Generic sort based on insertion into red-black trees. The first argument is the order for the elements.

setInsertEquivalence :: (a → a → Bool) → RedBlackTree a → RedBlackTree a

For compatibility with old version only

A.3.6 Library SCC

Computing strongly connected components
Copyright (c) 2000 - 2003, Wolfgang Lux See LICENSE for the full license.
The function scc computes the strongly connected components of a list of entities in two steps. First, the list is topologically sorted "downwards" using the defines relation. Then the resulting list is sorted "upwards" using the uses relation and partitioned into the connected components. Both relations are computed within this module using the bound and free names of each declaration. In order to avoid useless recomputations, the code in the module first decorates the declarations with their bound and free names and a unique number. The latter is only used to provide a trivial ordering so that the declarations can be used as set elements.

Exported functions:

scc :: (a → [b]) → (a → [b]) → [a] → [[a]]

Computes the strongly connected components of a list of entities. To be flexible, we distinguish the nodes and the entities defined in this node.

A.3.7 Library SearchTree

This library defines a representation of a search space as a tree and various search strategies on this tree. This module implements strong encapsulation as discussed in the JFLP’04 paper.

Exported types:

type Strategy a = SearchTree a → ValueSequence a

A search strategy maps a search tree into some sequence of values. Using the abstract type of sequence of values (rather than list of values) enables the use of search strategies for encapsulated search with search trees (strong encapsulation) as well as with set functions (weak encapsulation).
data SearchTree

A search tree is a value, a failure, or a choice between two search trees.

Exported constructors:

- Value :: a → SearchTree a
- Fail :: Int → SearchTree a
- Or :: (SearchTree a) → (SearchTree a) → SearchTree a

Exported functions:

getSearchTree :: a → IO (SearchTree a)

Returns the search tree for some expression.

someSearchTree :: a → SearchTree a

Internal operation to return the search tree for some expression. Note that this operation is not purely declarative since the ordering in the resulting search tree depends on the ordering of the program rules.

isDefined :: a → Bool

Returns True iff the argument is defined, i.e., has a value.

showSearchTree :: SearchTree a → String

Shows the search tree as an intended line structure

searchTreeSize :: SearchTree a → (Int,Int,Int)

Returns the size (number of Value/Fail/Or nodes) of the search tree.

limitSearchTree :: Int → SearchTree a → SearchTree a

Limit the depth of a search tree. Branches which a depth larger than the first argument are replace by Fail (-1).

deepfirstStrategy :: SearchTree a → ValueSequence a

Depth-first search strategy.

breadthfirstStrategy :: SearchTree a → ValueSequence a

Breadth-first search strategy.

iterativeDeepeningStrategy :: SearchTree a → ValueSequence a

Iterative-deepening search strategy.

iterativeDeepeningStrategy :: Int → (Int → Int) → SearchTree a → ValueSequence a
Parameterized iterative-deepening search strategy. The first argument is the initial depth bound and the second argument is a function to increase the depth in each iteration.

**diagStrategy ::** SearchTree a → ValueSequence a

Diagonalization search strategy.

**allValuesWith :: (SearchTree a → ValueSequence a) → SearchTree a → [a]**

Return all values in a search tree via some given search strategy.

**allValuesDFS ::** SearchTree a → [a]

Return all values in a search tree via depth-first search.

**allValuesBFS ::** SearchTree a → [a]

Return all values in a search tree via breadth-first search.

**allValuesIDS ::** SearchTree a → [a]

Return all values in a search tree via iterative-deepening search.

**allValuesIDSwith :: Int → (Int → Int) → SearchTree a → [a]**

Return all values in a search tree via iterative-deepening search. The first argument is the initial depth bound and the second argument is a function to increase the depth in each iteration.

**allValuesDiag ::** SearchTree a → [a]

Return all values in a search tree via diagonalization search strategy.

**getAllValuesWith :: (SearchTree a → ValueSequence a) → a → IO [a]**

Gets all values of an expression w.r.t. a search strategy. A search strategy is an operation to traverse a search tree and collect all values, e.g., *dfsStrategy* or *bfsStrategy*. Conceptually, all values are computed on a copy of the expression, i.e., the evaluation of the expression does not share any results.

**printAllValuesWith :: (SearchTree a → ValueSequence a) → a → IO ()**

Prints all values of an expression w.r.t. a search strategy. A search strategy is an operation to traverse a search tree and collect all values, e.g., *dfsStrategy* or *bfsStrategy*. Conceptually, all printed values are computed on a copy of the expression, i.e., the evaluation of the expression does not share any results.

**printValuesWith :: (SearchTree a → ValueSequence a) → a → IO ()**

Prints the values of an expression w.r.t. a search strategy on demand by the user. Thus, the user must type `<enter>` before another value is computed and printed. A search strategy is an operation to traverse a search tree and collect all values, e.g., *dfsStrategy* or *bfsStrategy*. Conceptually, all printed values are computed on a copy of the expression, i.e., the evaluation of the expression does not share any results.
someValue :: a → a

Returns some value for an expression.

Note that this operation is not purely declarative since the computed value depends on the ordering of the program rules. Thus, this operation should be used only if the expression has a single value. It fails if the expression has no value.

someValueWith :: (SearchTree a → ValueSequence a) → a → a

Returns some value for an expression w.r.t. a search strategy. A search strategy is an operation to traverse a search tree and collect all values, e.g., dfsStrategy or bfsStrategy.

Note that this operation is not purely declarative since the computed value depends on the ordering of the program rules. Thus, this operation should be used only if the expression has a single value. It fails if the expression has no value.

A.3.8 Library SearchTreeTraversal

Implements additional traversals on search trees.

Exported functions:

depthDiag :: SearchTree a → [a]

diagonalized depth first search.

rndDepthDiag :: Int → SearchTree a → [a]

randomized variant of diagonalized depth first search.

levelDiag :: SearchTree a → [a]

diagonalization of devels.

rndLevelDiag :: Int → SearchTree a → [a]

randomized diagonalization of levels.

rndLevelDiagFlat :: Int → Int → SearchTree a → [a]

randomized diagonalization of levels with flattening.

A.3.9 Library SetRBT

Library with an implementation of sets as red-black trees. All the operations on sets are generic, i.e., one has to provide an explicit order predicate (<) (less-than) on elements.

Exported types:

type SetRBT a = RedBlackTree a
Exported functions:

emptySetRBT :: (a → a → Bool) → RedBlackTree a

Returns an empty set, i.e., an empty red-black tree augmented with an order predicate.

isEmptySetRBT :: RedBlackTree a → Bool

Test for an empty set.

elemRBT :: a → RedBlackTree a → Bool

Returns true if an element is contained in a (red-black tree) set.

insertRBT :: a → RedBlackTree a → RedBlackTree a

Inserts an element into a set if it is not already there.

insertMultiRBT :: a → RedBlackTree a → RedBlackTree a

Inserts an element into a multiset. Thus, the same element can have several occurrences in the multiset.

deleteRBT :: a → RedBlackTree a → RedBlackTree a

delete an element from a set. Deletes only a single element from a multi set

setRBT2list :: RedBlackTree a → [a]

Transforms a (red-black tree) set into an ordered list of its elements.

unionRBT :: RedBlackTree a → RedBlackTree a → RedBlackTree a

Computes the union of two (red-black tree) sets. This is done by inserting all elements of the first set into the second set.

intersectRBT :: RedBlackTree a → RedBlackTree a → RedBlackTree a

Computes the intersection of two (red-black tree) sets. This is done by inserting all elements of the first set contained in the second set into a new set, which order is taken from the first set.

sortRBT :: (a → a → Bool) → [a] → [a]

Generic sort based on insertion into red-black trees. The first argument is the order for the elements.

A.3.10 Library Sort

A collection of useful functions for sorting and comparing characters, strings, and lists.
Exported functions:

sort :: [a] → [a]

The default sorting operation, mergeSort, with standard ordering <=.

sortBy :: (a → a → Bool) → [a] → [a]

The default sorting operation: mergeSort

sorted :: [a] → Bool

sorted xs is satisfied if the elements xs are in ascending order.

sortedBy :: (a → a → Bool) → [a] → Bool

sortedBy leq xs is satisfied if all adjacent elements of the list xs satisfy the ordering predicate leq.

permSort :: [a] → [a]

Permutation sort with standard ordering <=. Sorts a list by finding a sorted permutation of the input. This is not a usable way to sort a list but it can be used as a specification of other sorting algorithms.

permSortBy :: (a → a → Bool) → [a] → [a]

Permutation sort with ordering as first parameter. Sorts a list by finding a sorted permutation of the input. This is not a usable way to sort a list but it can be used as a specification of other sorting algorithms.

insertionSort :: [a] → [a]

Insertion sort with standard ordering <=. The list is sorted by repeated sorted insertion of the elements into the already sorted part of the list.

insertionSortBy :: (a → a → Bool) → [a] → [a]

Insertion sort with ordering as first parameter. The list is sorted by repeated sorted insertion of the elements into the already sorted part of the list.

quickSort :: [a] → [a]

Quicksort with standard ordering <=. The classical quicksort algorithm on lists.

quickSortBy :: (a → a → Bool) → [a] → [a]

Quicksort with ordering as first parameter. The classical quicksort algorithm on lists.

mergeSort :: [a] → [a]

Bottom-up mergesort with standard ordering <=.

mergeSortBy :: (a → a → Bool) → [a] → [a]
Bottom-up mergesort with ordering as first parameter.

\[
\text{leqList} :: (a \to a \to \text{Bool}) \to [a] \to [a] \to \text{Bool}
\]
Less-or-equal on lists.

\[
\text{cmpList} :: (a \to a \to \text{Ordering}) \to [a] \to [a] \to \text{Ordering}
\]
Comparison of lists.

\[
\text{leqChar} :: \text{Char} \to \text{Char} \to \text{Bool}
\]
Less-or-equal on characters (deprecated, use Prelude.\leq/\leq).

\[
\text{cmpChar} :: \text{Char} \to \text{Char} \to \text{Ordering}
\]
Comparison of characters (deprecated, use Prelude.compare).

\[
\text{leqCharIgnoreCase} :: \text{Char} \to \text{Char} \to \text{Bool}
\]
Less-or-equal on characters ignoring case considerations.

\[
\text{leqString} :: \text{String} \to \text{String} \to \text{Bool}
\]
Less-or-equal on strings (deprecated, use Prelude.\leq/\leq).

\[
\text{cmpString} :: \text{String} \to \text{String} \to \text{Ordering}
\]
Comparison of strings (deprecated, use Prelude.compare).

\[
\text{leqStringIgnoreCase} :: \text{String} \to \text{String} \to \text{Bool}
\]
Less-or-equal on strings ignoring case considerations.

\[
\text{leqLexGerman} :: \text{String} \to \text{String} \to \text{Bool}
\]
Lexicographical ordering on German strings. Thus, upper/lowercase are not distin-
guished and Umlauts are sorted as vocals.

A.3.11 Library TableRBT

Library with an implementation of tables as red-black trees:
A table is a finite mapping from keys to values. All the operations on tables are generic, i.e., one has
to provide an explicit order predicate ("\text{cmp}" below) on elements. Each inner node in the red-black
tree contains a key-value association.

Exported types:

\[
\text{type TableRBT a b = RedBlackTree (a,b)}
\]
Exported functions:

emptyTableRBT :: (a → a → Bool) → RedBlackTree (a,b)

Returns an empty table, i.e., an empty red-black tree.

isEmptyTable :: RedBlackTree (a,b) → Bool

tests whether a given table is empty

lookupRBT :: a → RedBlackTree (a,b) → Maybe b

Looks up an entry in a table.

updateRBT :: a → b → RedBlackTree (a,b) → RedBlackTree (a,b)

Inserts or updates an element in a table.

tableRBT2list :: RedBlackTree (a,b) → [(a,b)]

Transforms the nodes of red-black tree into a list.

deleteRBT :: a → RedBlackTree (a,b) → RedBlackTree (a,b)

A.3.12 Library Traversal

Library to support lightweight generic traversals through tree-structured data. See here\(^{13}\) for a description of the library.

Exported types:

type Traversable a b = a → ([b],[b] → a)

A datatype is Traversable if it defines a function that can decompose a value into a list of children of the same type and recombine new children to a new value of the original type.

Exported functions:

noChildren :: a → ([b],[b] → a)

Traversal function for constructors without children.

children :: (a → ([b],[b] → a)) → a → [b]

Yields the children of a value.

replaceChildren :: (a → ([b],[b] → a)) → a → [b] → a

Replaces the children of a value.

\(^{13}\)http://www-ps.informatik.uni-kiel.de/~sebf/projects/traversal.html
mapChildren :: (a → ([b],[b] → a)) → (b → b) → a → a

Applies the given function to each child of a value.

cfamily :: (a → ([a],[a] → a)) → a → [a]

Computes a list of the given value, its children, those children, etc.

cchildFamilies :: (a → ([b],[b] → a)) → (b → ([b],[b] → b)) → a → [b]

Computes a list of family members of the children of a value. The value and its children can have different types.

cmapFamily :: (a → ([a],[a] → a)) → (a → a) → a → a

Applies the given function to each member of the family of a value. Proceeds bottom-up.

cmapChildFamilies :: (a → ([b],[b] → a)) → (b → ([b],[b] → b)) → (b → b) → a → a

Applies the given function to each member of the families of the children of a value. The value and its children can have different types. Proceeds bottom-up.

cevalFamily :: (a → ([a],[a] → a)) → (a → Maybe a) → a → a

Applies the given function to each member of the family of a value as long as possible. On each member of the family of the result the given function will yield Nothing. Proceeds bottom-up.

cevalChildFamilies :: (a → ([b],[b] → a)) → (b → ([b],[b] → b)) → (b → Maybe b) → a → a

Applies the given function to each member of the families of the children of a value as long as possible. Similar to cevalFamily.

cfold :: (a → ([a],[a] → a)) → (a → [b] → b) → a → b

Implements a traversal similar to a fold with possible default cases.

cfoldChildren :: (a → ([b],[b] → a)) → (b → ([b],[b] → b)) → (a → [c] → d) → (b → [c] → c) → a → d

Fold the children and combine the results.

creplaceChildrenIO :: (a → ([b],[b] → a)) → a → IO [b] → IO a

IO version of replaceChildren

cmapChildrenIO :: (a → ([b],[b] → a)) → (b → IO b) → a → IO a

IO version of mapChildren

cmapFamilyIO :: (a → ([a],[a] → a)) → (a → IO a) → a → IO a

177
IO version of mapFamily

\[
\text{mapChildFamiliesIO} :: (a \to ([b],[b] \to a)) \to (b \to ([b],[b] \to b)) \to (b \to \text{IO} b) \to a \to \text{IO} a
\]

IO version of evalFamily

\[
\text{evalFamilyIO} :: (a \to ([a],[a] \to a)) \to (a \to \text{IO} (\text{Maybe} a)) \to a \to \text{IO} a
\]

IO version of evalChildFamilies

\[
\text{evalChildFamiliesIO} :: (a \to ([b],[b] \to a)) \to (b \to ([b],[b] \to b)) \to (b \to \text{IO} (\text{Maybe} b)) \to a \to \text{IO} a
\]

A.3.13 Library UnsafeSearchTree

This library defines a representation of a search space as a tree and various search strategies on this tree. This module implements strong encapsulation as discussed in this paper. Warning: In contrast to the SearchTree Module, free variables that are not bound in the encapsulated expression remain free! This may lead to non-determinism if such an escaped variable is bound later via pattern matching.

Exported types:

\[
\text{type Strategy a} = \text{SearchTree a} \to \text{ValueSequence a}
\]

data SearchTree

A search tree is a value, a failure, or a choice between two search trees.

Exported constructors:

- Value :: a \to SearchTree a
- Fail :: Int \to SearchTree a
- Or :: (SearchTree a) \to (SearchTree a) \to SearchTree a

Exported functions:

isVar :: a \to Bool

Tests whether the argument is a free variable. This function is only meaningful when applied to a part of a result of an encapsulated expression if the argument stems from a Value node of a SearchTree.

declaredVars :: a \to a \to Bool
Tests whether both arguments are identical free variables. This function is only meaningful when applied to parts of a result of an encapsulated expression if the argument stems from a Value node of a SearchTree.

\[ \text{varId :: } a \rightarrow \text{Int} \]

Returns the unique identifier of a free variable, if the argument was not a free variable, otherwise an error is raised. This function is only meaningful when applied to a part of a result of an encapsulated expression if the argument stems from a Value node of a SearchTree.

\[ \text{getSearchTree :: } a \rightarrow \text{IO (SearchTree a)} \]

Returns the search tree for some expression.

\[ \text{someSearchTree :: } a \rightarrow \text{SearchTree a} \]

Internal operation to return the search tree for some expression. Note that this operation is not purely declarative since the ordering in the resulting search tree depends on the ordering of the program rules.

\[ \text{isDefined :: } a \rightarrow \text{Bool} \]

Returns True iff the argument is is defined, i.e., has a value.

\[ \text{showSearchTree :: SearchTree a } \rightarrow \text{String} \]

Shows the search tree as an intended line structure.

\[ \text{searchTreeSize :: SearchTree a } \rightarrow \text{(Int,Int,Int)} \]

Return the size (number of Value/Fail/Or nodes) of the search tree.

\[ \text{allValuesDFS :: SearchTree a } \rightarrow \text{[a]} \]

Return all values in a search tree via depth-first search.

\[ \text{dfsStrategy :: SearchTree a } \rightarrow \text{ValueSequence a} \]

\[ \text{allValuesBFS :: SearchTree a } \rightarrow \text{[a]} \]

Return all values in a search tree via breadth-first search.

\[ \text{bfsStrategy :: SearchTree a } \rightarrow \text{ValueSequence a} \]

\[ \text{allValuesIDS :: SearchTree a } \rightarrow \text{[a]} \]

Return all values in a search tree via iterative-deepening search.

\[ \text{idsStrategy :: SearchTree a } \rightarrow \text{ValueSequence a} \]
allValuesIDSwith :: Int → (Int → Int) →SearchTree a → [a]

Return the list of all values in a search tree via iterative-deepening search. The first argument is the initial depth bound and the second argument is a function to increase the depth in each iteration.

idsStrategyWith :: Int → (Int → Int) →SearchTree a → ValueSequence a

Return all values in a search tree via iterative-deepening search. The first argument is the initial depth bound and the second argument is a function to increase the depth in each iteration.

getAllValuesWith :: (SearchTree a → ValueSequence a) → a → IO [a]

Gets all values of an expression w.r.t. a search strategy. A search strategy is an operation to traverse a search tree and collect all values, e.g., dfsStrategy or bfsStrategy. Conceptually, all values are computed on a copy of the expression, i.e., the evaluation of the expression does not share any results. Moreover, the evaluation suspends as long as the expression contains unbound variables.

someValue :: a → a

Returns some value for an expression.

Note that this operation is not purely declarative since the computed value depends on the ordering of the program rules. Thus, this operation should be used only if the expression has a single value. It fails if the expression has no value.

someValueWith :: (SearchTree a → ValueSequence a) → a → a

Returns some value for an expression w.r.t. a search strategy. A search strategy is an operation to traverse a search tree and collect all values, e.g., dfsStrategy or bfsStrategy.

Note that this operation is not purely declarative since the computed value depends on the ordering of the program rules. Thus, this operation should be used only if the expression has a single value. It fails if the expression has no value.

A.3.14 Library ValueSequence

This library defines a data structure for sequence of values. It is used in search trees (moduleSearchTree) as well as in set functions (module SetFunctions). Using sequence of values (rather than standard lists of values) is necessary to get the behavior of set functions w.r.t. finite failures right, as described in the paper

Exported types:

\[
\text{data ValueSequence}
\]

A value sequence is an abstract sequence of values. It also contains failure elements in order to implement the semantics of set functions w.r.t. failures in the intended manner.

Exported constructors:

Exported functions:

\[
\text{emptyVS :: ValueSequence a}
\]

An empty sequence of values.

\[
\text{addVS :: a → ValueSequence a → ValueSequence a}
\]

Adds a value to a sequence of values.

\[
\text{failVS :: Int → ValueSequence a}
\]

Adds a failure to a sequence of values. The argument is the encapsulation level of the failure.

\[
(\mid++\mid) :: \text{ValueSequence a → ValueSequence a → ValueSequence a}
\]

Concatenates two sequences of values.

\[
\text{vsToList :: ValueSequence a → [a]}
\]

Transforms a sequence of values into a list of values.
B Markdown Syntax

This document describes the syntax of texts containing markdown elements. The markdown syntax is intended to simplify the writing of texts whose source is readable and can be easily formatted, e.g., as part of a web document. It is a subset of the original markdown syntax (basically, only internal links and pictures are missing) supported by the Curry library Markdown.

B.1 Paragraphs and Basic Formatting

Paragraphs are separated by at least one line which is empty or does contain only blanks. Inside a paragraph, one can emphasize text or also strongly emphasize text. This is done by wrapping it with one or two _ or * characters:

_emphasize_
*emphasize*
__strong__
**strong**

Furthermore, one can also mark program code text by backtick quotes (‘):

The function ‘fib’ computes Fibonacci numbers.

Web links can be put in angle brackets, like in the link http://www.google.com:

<http://www.google.com>

Currently, only links starting with 'http' are recognized (so that one can also use HTML markup). If one wants to put a link under a text, one can put the text in square brackets directly followed by the link in round brackets, as in Google:

[Google](http://www.google.com)

If one wants to put a character that has a specific meaning in the syntax of Markdown, like * or _, in the output document, it should be escaped with a backslash, i.e., a backslash followed by a special character in the source text is translated into the given character (this also holds for program code, see below). For instance, the input text

/_word_/

produces the output "_word_". The following backslash escapes are recognized:

\backslash
\backtick
*asterisk
_:underscore
{}curly braces
[]square brackets
B.2 Lists and Block Formatting

An unordered list (i.e., without numbering) is introduced by putting a star in front of the list elements (where the star can be preceded by blanks). The individual list elements must contain the same indentation, as in

* First list element
  with two lines

* Next list element.

 It contains two paragraphs.

* Final list element.

This is formatted as follows:

- First list element with two lines
- Next list element.
  It contains two paragraphs.
- Final list element.

Instead of a star, one can also put dashes or plus to mark unordered list items. Furthermore, one could nest lists. Thus, the input text

- Color:
  + Yellow
  + Read
  + Blue
- BW:
  + Black
  + White

is formatted as

- Color:
– Yellow
– Read
– Blue

• BW:
  – Black
  – White

Similarly, ordered lists (i.e., with numbering each item) are introduced by a number followed by a dot and at least one blank. All following lines belonging to the same numbered item must have the same indent as the first line. The actual value of the number is not important. Thus, the input

1. First element

99. Second
   element

is formatted as

1. First element

2. Second element

A quotation block is marked by putting a right angle followed by a blank in front of each line:

> This is
> a quotation.

It will be formatted as a quote element:

This is a quotation.

A block containing program code starts with a blank line and is marked by intending each input line by at least four spaces where all following lines must have at least the same indentation as the first non-blank character of the first line:

\[
f x y = \text{let } z = (x,y) \\
\quad \text{in } (z,z)
\]

The indentation is removed in the output:

\[
f x y = \text{let } z = (x,y) \\
\quad \text{in } (z,z)
\]

To visualize the structure of a document, one can also put a line containing only blanks and at least three dashes (stars would also work) in the source text:

--------------------------------------------------

This is formatted as a horizontal line:
B.3 Headers

The are two forms to mark headers. In the first form, one can "underline" the main header in the source text by equal signs and the second-level header by dashes:

First-level header
==================
Second-level header
-------------------

Alternatively (and for more levels), one can prefix the header line by up to six hash characters, where the number of characters corresponds to the header level (where level 1 is the main header):

# Main header

## Level 2 header

### Level 3

#### Level 4

##### Level 5

###### Level 6
C SQL Syntax Supported by CurryPP

This section contains a grammar in EBNF which specifies the SQL syntax recognized by the Curry preprocessor in integrated SQL code (see Sect. 12.4). The grammar satisfies the LL(1) property and is influenced by the SQLite dialect.\(^1\)

190
D Auxiliary Files

During the translation and execution of a Curry program with KiCS2, various intermediate representations of the source program are created and stored in different files which are shortly explained in this section. If you use KiCS2, it is not necessary to know about these auxiliary files because they are automatically generated and updated. You should only remember the command for deleting all auxiliary files (“cleancurry”, see Section 1.2) to clean up your directories.

The various components of KiCS2 create the following auxiliary files.

prog.fcy: This file contains the Curry program in the so-called “FlatCurry” representation where all functions are global (i.e., lambda lifting has been performed) and pattern matching is translated into explicit case/or expressions (compare Appendix A.1). This representation might be useful for other back ends and compilers for Curry and is the basis doing metaprogramming in Curry. This file is implicitly generated when a program is compiled with KiCS2. It can be also explicitly generated by the front end of KiCS2:

```
kics2 frontend --flat -i kics2home/lib prog
```

The FlatCurry representation of a Curry program is usually generated by the front-end after parsing, type checking and eliminating local declarations.

If the Curry module \( M \) is stored in the directory \( \text{dir} \), the corresponding FlatCurry program is stored in the directory “\( \text{dir}/.curry \)”. This is also the case for hierarchical module names: if the module \( D1.D2.M \) is stored in the directory \( \text{dir} \) (i.e., the module is actually stored in \( \text{dir}/D1/D2/M.curry \)), then the corresponding FlatCurry program is stored in “\( \text{dir}/.curry/D1/D2/M.fcy \)”.

prog.fint: This file contains the interface of the program in the so-called “FlatCurry” representation, i.e., it is similar to prog.fcy but contains only exported entities and the bodies of all functions omitted (i.e., “external”). This representation is useful for providing a fast access to module interfaces. This file is implicitly generated when a program is compiled with KiCS2 and stored in the same directory as prog.fcy.

Curry_prog.hs: This file contains a Haskell program as the result of translating the Curry program with the KiCS2 compiler.

If the Curry module \( M \) is stored in the directory \( \text{dir} \), the corresponding Haskell program is stored in the directory “\( \text{dir}/.curry/kics2 \)”. This is also the case for hierarchical module names: if the module \( D1.D2.M \) is stored in the directory \( \text{dir} \) (i.e., the module is actually stored in \( \text{dir}/D1/D2/M.curry \)), then the corresponding Haskell program is stored in “\( \text{dir}/.curry/kics2/D1/D2/Curry_prog.hs \)”.

Curry_prog.hi: This file contains the interface of the Haskell program Curry_prog.hs when the latter program is compiled in order to execute it. This file is stored in the same directory as Curry_prog.hs.

Curry_prog.o: This file contains the object code of the Haskell program Curry_prog.hs when the latter program is compiled in order to execute it. This file is stored in the same directory as Curry_prog.hs.
**Curry_prog.nda:** This file contains some information about the determinism behavior of operations that is used by the KiCS2 compiler (see [11] for more details about the use of this information). This file is stored in the same directory as Curry_prog.hs.

**Curry_prog.info:** This file contains some information about the top-level functions of module prog that are used by the interactive environment, like determinism behavior or IO status. This file is stored in the same directory as Curry_prog.hs.

**prog:** This file contains the executable after compiling and saving a program with KiCS2 (see command “:save” in Section 2.2).
E External Operations

Currently, KiCS2 has no general interface to external operations, i.e., operations whose semantics is not defined by program rules in a Curry program but by some code written in another programming language. Thus, if an external operation should be added to the system, this operation must be declared as `external` in the Curry source code and an implementation for this external operation must be provided for the run-time system. An external operation is defined as follows in the Curry source code:

1. Add a type declaration for the external operation somewhere in a module defining this operation (usually, the prelude or some system module).

2. For external operations it is not allowed to define any rule since their semantics is determined by an external implementation. Instead of the defining rules, you have to write

   ```haskell
   f external
   ```

   below the type declaration for the external operation `f`.

Furthermore, an implementation of the external operation must be provided in the target language of the KiCS2 compiler, i.e., in Haskell, and inserted in the compiled code. In order to simplify this task, KiCS2 follows some code conventions that are described in the following.

Assume you want to implement your own concatenation for strings in a module `String`. The name and type of this string concatenation should be

```haskell
sconc :: String → String → String
```

Since the primitive Haskell implementation of this operation does not know anything about the operational mechanism of Curry (e.g., needed narrowing, non-deterministic rewriting), the arguments need to be completely evaluated before the primitive implementation is called. This can be easily obtained by the prelude operation (`##`) that applies an operation to the normal form of the given argument, i.e., this operation evaluates the argument to its normal form before applying the operation to it.\(^\text{15}\) Thus, we define `sconc` by

```haskell
sconc s1 s2 = (prim_sconc ## s1) ## s2
```

```haskell
prim_sconc :: String → String → String
prim_sconc external
```

so that it is ensured that the external operation `prim_sconc` is always called with complete evaluated arguments.

In order to define the Haskell code implementing `prim_sconc`, one has to satisfy the naming conventions of KiCS2. The KiCS2 compiler generates the following code for the external operation `prim_sconc` (note that the generated Haskell code for the module `String` is stored in the file `.curry/kics2/Curry_String.hs`):

\(^{15}\)There is also a similar prelude operation (`#`) which evaluates the argument only to head-normal form. This is a bit more efficient and can be used for unstructured types like `Bool`.
The type constructors OP_List and C_Char of the prelude Curry_Prelude correspond to the Curry type constructors for lists and characters. The Haskell operation external_d_C_prim_sconc is the external operation to be implemented in Haskell by the programmer. The additional argument of type ConstStore represents the current set of constraints when this operation is called. This argument is intended to provide a more efficient access to binding constraints and can be ignored in standard operations.

If String.curry contains the code of the Curry function sconc described above, the Haskell code implementing the external operations occurring in the module String must be in the file External[String].hs which is located in the same directory as the file String.curry. The KiCS2 compiler appends the code contained in External[String].hs to the generated code stored in the file .curry/kics2/Curry[String].hs.17

In order to complete our example, we have to write into the file External[String].hs a definition of the Haskell function external_d_C_prim_sconc. Thus, we start with the following definitions:

import qualified Curry_Prelude as CP

external_d_C_prim_sconc :: CP.OP_List CP.C_Char → CP.OP_List CP.C_Char → ConstStore → CP.OP_List CP.C_Char

d_C_prim_sconc x1 x2 x3500 = external_d_C_prim_sconc x1 x2 x3500

First, we import the standard prelude with the name CP in order to shorten the writing of type declarations. In order to write the final code of this operation, we have to convert the Curry-related types (like C_Char) into the corresponding Haskell types (like Char). Note that the Curry-related types contain information about non-deterministic or constrained values (see \[11, 12\]) that are meaningless in Haskell. To solve this conversion problem, the implementation of KiCS2 provides a family of operations to perform these conversions for the predefined types occurring in the standard prelude. For instance, fromCurry converts a Curry type into the corresponding Haskell type, and toCurry converts the Haskell type into the corresponding Curry type. Thus, we complete our example with the definition (note that we simply ignore the final argument representing the constraint store)

external_d_C_prim_sconc s1 s2 _ = toCurry ((fromCurry s1 ++ fromCurry s2) :: String)

Here, we use Haskell’s concatenation operation “++” to concatenate the string arguments. The type annotation “:: String” is necessary because “++” is a polymorphic function so that the type inference system of Haskell has problems to determine the right instance of the conversion function.

The conversion between Curry types and Haskell types, i.e., the family of conversion operation fromCurry and toCurry, is defined in the KiCS2 implementation for all standard data types. In particular, it is also defined on function types so that one can easily implement external Curry I/O

\[\text{Note that all translated Curry modules are imported in the Haskell code fully qualified in order to avoid name conflicts.}\]

\[\text{If the file External[String].hs contains also some import declarations at the beginning, these import declarations are put after the generated import declarations.}\]
actions by using Haskell I/O actions. For instance, if we want to implement an external operation to print some string as an output line, we start by declaring the external operations in the Curry module `String`:

```haskell
printString :: String → IO ()
printString s = prim_printString $## s

prim_printString :: String → IO ()
prim_printString external
```

Next we add the corresponding implementation in the file `External_String.hs` (where `C_IO` and `OP_Unit` are the names of the Haskell representation of the Curry type constructor `IO` and the Curry data type “()”, respectively):

```haskell
external_d_C_prim_printString :: CP.OP_List CP.C_Char → ConstStore → CP.C_IO CP.OP_Unit

external_d_C_prim_printString s _ = toCurry putStrLn s
```

Here, Haskell’s I/O action `putStrLn` of type “`String → IO ()`” is transformed into a Curry I/O action “`toCurry putStrLn`” which has the type

```
CP.OP_List CP.C_Char → CP.C_IO CP.OP_Unit
```

When we compile the Curry module `String`, KiCS2 combines these definitions in the target program so that we can immediately use the externally defined operation `printString` in Curry programs.

As we have seen, KiCS2 transforms a name like `primOP` of an external operation into the name `external_d_C_primOP` for the Haskell operation to be implemented, i.e., only a specific prefix is added. However, this is only valid if no special characters occur in the Curry names. Otherwise (in order to generate a correct Haskell program), special characters are translated into specific names prefixed by “`OP_`”. For instance, if we declare the external operation

```
(<&>) :: Int → Int → Int
(<&>) external
```

the generated Haskell module contains the code

```haskell
d_OP_lt_ampersand_gt :: Curry_Prelude.C_Int → Curry_Prelude.C_Int → ConstStore → Curry_Prelude.C_Int
d_OP_lt_ampersand_gt x1 x2 x3500 = external_d_OP_lt_ampersand_gt x1 x2 x3500
```

so that one has to implement the operation `external_d_OP_lt_ampersand_gt` in Haskell. If in doubt, one should look into the generated Haskell code about the names and types of the operations to be implemented.

Finally, note that this method to connect functions implemented in Haskell to Curry programs provides the opportunity to connect also operations written in other programming languages to Curry via Haskell’s foreign function interface.
